THE NEOTROPICAL ORB-WEAVER GENUS METAZYGIA (ARANEAE: ARANEIDAE)

HERBERT W. LEVI

ABSTRACT. Metazygia are Neotropical nocturnal orb weavers. Many species are small, less than 5 mm total length. They are found from the southeastern United States to Argentina, but most species occur in the Amazon area and southeastern South America. Although lacking a paramedian apophysis in the male palpus, they exhibit other characters that suggest that they be grouped (together with Eustala) close to Alpida.

There are 86 Neotropical species: 68 new (79%) and only 18 previously known (21%). Also, there are two Nearctic species, M. carolinalis and M. culic, making a total of 88 species of Metazygia. Of the 68 new species, 18 are known from both sexes, 16 from the male only, and 34 from the female only. Six names are synonymized for the first time.

The females of all species are believed to rest in a retreat at the side of the web during daytime, and many build the orb with an open sector adjacent to the retreat.

INTRODUCTION

This is one of a series of revisions of Neotropical orb weavers (complete list in Levi, 1993b). These revisions should make it possible for researchers to identify Neotropical orb weavers, not possible earlier as some previously described species had never been illustrated and males had not been matched to females. Examining and illustrating the holotype specimens of old names is one of the most important tasks of the revisor. After all the genera of the family have been revised, the relationship of the genera to each other can be studied.

METHODS AND MATERIALS

The methods have been described in detail in Levi (1993b). As in previous papers, eye sizes are expressed as ratios, comparing the diameter of the measured eye (with cornea in profile) to that of the anterior median eyes (Levi, 1993b, figs. 27, 28). Distances between eyes of the anterior row are expressed as diameters of the anterior median eyes (in profile); distances between eyes of the posterior row are given as diameters of the posterior median eyes. The height of the clypeus (the distance between the lower edge of the anterior median eyes and the edge of the carapace) is given in diameters of an anterior median eye (Levi, 1993b, fig. 28f). These measurements are approximate, as araneid eyes are variable and difficult to measure accurately.

Secondary Homonyms. The superb spider catalogs by Petrunkevitch, Roewer, and Bonnet, which so greatly facilitate the work of systematists, lumped genera. As a result of lumping genera, secondary homonyms are created: specific names that are unique in their own genera turn out to be homonyms when placed in the large genera Aranea or Araneus, having been used with Aranea or Araneus previously.

Petrunkevitch (1911) and also Roewer (1942) made new names for the secondary homonyms. I have dismissed these new names when returning species to their previous genera. In this I have followed other authors. For example, Petrunkevitch (1911) lumped 18 genera, replacing Singa moesta with metuens, Singa maculata with tusus, and Singa variabilis with varians, among others. These Petrunkevitch replacement names have not been used in Comstock (1912), Gertsch (Comstock, rev. edit.)
Gertsch 1940), or Kaston (1948). All have tried to avoid name changes.

According to Article 59 of the International Code of Zoological Nomenclature (ICZN, 1985), a junior secondary homonym replaced before 1961 is permanently invalid. Article 59b says that if the replacement name for such a junior secondary homonym is the cause of confusion, then the case is to be referred to the Commission. Article 59d says "a species group name rejected after 1960 on grounds of junior secondary homonymy is to be reinstated by anyone who believes the two species group taxa in question are not congeneric..." The newer method (59d) has been used by American arachnologists all along and has avoided confusion.

Roewer (1942, 1955) replaced some secondary homonyms cited in this revision (e.g., *Aranea palloides* Roewer for *Metazygia pallidula*, *Aranea errans* for *Metazygia erratica*). But Roewer had the good judgment not to use Petrunkevitch's replacement names (e.g., for *Singa*). Also, Bonnet (1955–59) did not use the replacement names of Petrunkevitch when returning species to their original genera (e.g., Petrunkevitch changed *Zilla guttata* to *gemellus* when he placed it in *Araneus*, but the name is back to *Zilla guttata* in Bonnet, 1959). Perhaps the International Commissioners should make the rules more flexible.

It is unfortunate that many younger arachnologists still give their new species overworked names such as *pallida*, *maculata*, and *variabilis*, which are likely to have been used before in the same family or in related families and may be the cause for later discovery of secondary homonymy.

*Lectotypes*. As in previous papers, lectotypes have been designated when synotypes belonged to different species. They were not indicated routinely as an aspect of the revision; there is no requirement to do so (ICZN, 1985: Art. 74). A decision has to be made on whether to designate a male or a female as the lectotype. This choice may become critical later, if it is found that the presumed species actually consists of sibling species recognizable only in one sex, not in the other.

*Collections*. Specimens from the following collections were used. I thank the curators for making the material available for this study:

I would also like to thank R. Buskirk and W. Eberhard for natural history information and G. B. Edwards and P. Vanzolini for information on collecting sites. C. D. Dondale gave advice on a nomenclatural problem. Laura Leibensperger helped throughout and read the manuscript. L. R. Levi improved the wording. E. H. Buckup and two anonymous readers carefully read the manuscript and made
numerous corrections and improvements. D. Sherry helped with the final word processing. The research was started with the help of NSF grant BMS 75-05719. Publication costs of this study were covered in part by the Wetmore Colles Fund.

**Metazygia F. P.-Cambridge**

*Metazygia* F. P.-Cambridge, 1903: 501. Type species by original designation *M. wittfeldae* (McCook).

The gender of the name is feminine.

**Diagnosis.** *Metazygia* differs from other araneid genera by having a glabrous carapace with posterior median eyes that face up and almost touching each other, and an oval abdomen, that is widest at the middle (Figs. 5, 12).

In many species, but not all, the female has a round, laterally compressed scape on the ventral face of the epigynum (Figs. 1–4).

The palpus of the male has only one patellar seta and lacks a paramedian apophysis (Figs. 45, 112).

Contiguous posterior median eyes are found also in *Larinia* and *Cyclosa* and among some species of *Alpaida*, *Araneus*, *Aculepeira*, and *Dubiepeira*. *Larinia* differs from *Metazygia* by having an elongate abdomen. These genera (except *Alpaida*) differ from *Metazygia* by having the carapace setose and by the annulate scape. All except *Alpaida* and *Cyclosa* have two macrosetae on the palpal patella, and the male palpus has a distal hematodocha. *Cyclosa* differs by having the carapace narrow in the cephalic region. Both *Alpaida* and *Cyclosa* have a paramedian apophysis in the male palpus. *Metazygia* females can easily be confused with those of *Singa*, *Nuctenea* (*Larinioides*), and *Zyggiella* because of similar abdomen coloration and shape. These three genera are not found in the Neotropical region, although *Zyggiella x-notata* (Clerck) and *Larinioides sclopetaria* (Clerck) are common in Chile where they have been introduced. No *Metazygia* species are known from Chile. *Zyggiella* males differ from *Metazygia* by having a cone-shaped palpal tibia, as is common in tetragnathids; *Nuctenea* and *Larinioides* males have two palpal patellar macrosetae. Some *Metazygia* females have been confused with *Chrysosoma*, but this has tetragnathid characters (Levi, 1986). The species of these similar genera all make a tube-shaped, silken retreat.

It is possible to have doubts and misplace *Metazygia* species if only a female is available.

**Relationship.** *Metazygia* is closest to the genus *Eustala*. Shared apomorphies include the anteriorly projecting scape in some *Metazygia* females (Figs. 263, 270), the lateral placement of the median apophysis in the male palpus (M in Figs. 44, 45), and, in the palpus of larger species, a semitransparent blister below the distal prong of the terminal apophysis (B in Figs. 45, 46). In spite of these unusual shared characters, *Eustala* is distinguished by the position of the posterior median eyes, on a slight swelling and facing laterally, and by the shape of the abdomen, subtriangular to elongate, widest anteriorly and often with a median white streak on the underside. Also, the carapace of *Eustala* is setose, while that of *Metazygia* is glabrous (Table 1).

Both *Metazygia* and *Eustala*, although lacking a paramedian apophysis in the male palpus (Figs. 45, 112), have to be grouped near *Alpaida* and other genera having a paramedian apophysis. They mostly have only a single palpal patellar seta and the position of the conductor of the male palpus is usually on the inside face of the tegulum (and not on the outside rim of the tegulum as in *Araneus*-related genera). There is a relative absence of the distal hematodocha in the male palpus, a structure also prominent in *Araneus*-related genera. There is abundant pigment around the eyes in *Metazygia* species, as there is in *Alpaida* species. Many of the genera related to *Alpaida* (but not *Alpaida* or *Metazygia*) have abdomens with two or three posterior, median humps on the ab-

**P. bistriata** and E. nepheiloides (Levi, 1971) have a large macroseta and a smaller one on the male* palpal patella.

Bracketed characters are autapomorphies for the genus.

Abbreviations: abd., abdomen; ant., anterior; carap., carapace; ceph., cephalic; post., posterior(ly); prov., provisionally; reg., region; tuber(s), tubercle(s); v., venter. LE, lateral eyes; M, median apophysis; ME, median eyes; PM, paramedian apophysis; PME, posterior median eyes; Y, cymbium.

domen (Eriophora, Parawixia, Wagneriana, Acanthepeira, and also Eustala), a feature uncommon in any other spider. Perhaps the lack of paramedian apophysis and the sometimes intermediate position of the conductor (Fig. 112) indicate an intermediate relationship (Table 1).

Description. The cephalothorax is orange to orange-brown in alcohol, the legs rarely with dark rings. The abdomen has a characteristic folium pattern consisting of pairs of brackets (Figs. 5, 124) or sometimes a Zygiella-like pattern (Figs. 58, 110). The smallest species have a white (green or silvery when alive) abdomen with a black band around the anterior margin (Figs. 325, 330). The green color, which washes out in alcohol, is known for M. octama, M. serian, and M. lopez (Eberhard, personal communication). The black band around the anterior is not found in other Neotropical araneids. The carapace has few setae, and the median eye quadrangle is always narrower posteriorly (except in M. vaupes, where it is square). The anterior median eyes are slightly larger than the posterior medians, and the laterals are always the smallest. The height of the clypeus is less than the diameter of an anterior median eye. The eye region is usually all black but in some species lacks pigment (Fig. 336). The cephalic region of the carapace is more than half the width of the thoracic region; in M. uma (Fig. 224), it is almost equal in width.

The abdomen is oval, widest in the middle. In some small species, it is almost spherical (Figs. 306, 307); in some large species, almost cylindrical (Fig. 228). Sometimes the abdomen is anteriorly flattened (Fig. 317) or anteriorly projecting (Fig. 242) or has an anterior notch (M. vaupes, Fig. 301).

The males of three species have modified fangs (see later).

Genitalia. In the larger species, the epigynum has a laterally flattened scape, which is round in lateral view (Figs. 1-4, 69-71). The greatest diversity of epigynum occurs in the small species, where some even have a long scape (Figs. 322, 328). In many species, the scape appears to be torn off by the male after mating, and it may be unusual to find a female with the scape intact (Figs. 277-280). (Removal of the scape by the male may protect its sperm by preventing additional female matings.) Often it is not known whether there is a scar from a torn scape or the middle area is sculpture (Figs. 255-257, 365, 366). Part of the base of the epigynum is torn off in M. mundulella (Fig. 234) and may be missing also in M. saturnino (Figs. 197, 198) and M. amalla (Figs. 247, 248). While it is common for an araneid male to remove the scape, destruction of the base of the epigynum is not otherwise known in araneid spiders. In M. erratica, the opening of the epigynum is sealed with an amorphous black secretion that is difficult to remove (Figs. 370-372). A similar brown exudate may be present on the epigynum of M. lopez. In still other species, part of the male embolus breaks and plugs the opening of the epigynum (Fig. 40).

Internal female genitalia were examined in two pairs of species: M. wittfeldiae and M. dubiia, and M. zilloides and M. keyserlingi. No differences were found in the similar species that might be useful for determinations.

Male. Males of some small species have the carapace margin lobed above the first coxae (Figs. 384, 390), a modification not seen in males of other genera. All males have one macroseta on the palpal patella. Males of all except three species (M. gregalis, M. benella, and M. yobena) have a tooth on the endite that faces a tooth or tubercle at the proximal end of the palpal femur. These three species also have modified fangs: the fangs have a lobe (Figs. 261, 262, 269, 276), presumably to hold the female during mating. Metazygia gregalis also has the distal end of the chelicerae modified as a protecting flange (Fig. 261).

All species have a small hook on the distal margin of the first coxa, but if very small, the hook may have moved, to face
the second coxa. The second tibiae are usually thicker than the first and are armed with macrosetae. Males may have macrosetae on the first tibia, also. Some males have a short macroseta on the fourth coxa and sometimes on the third, as in related genera (those with one patellar macroseta).

Some species have a large terminal apophysis (A) in the palpus, with a terminal prong above a transparent blister (B in Figs. 45, 112); others have lost the terminal apophysis and have only one sclerite beyond the embolus (E) or none (Fig. 260). The part remaining with the embolus (Figs. 221, 230, 237) might be a reduced terminal apophysis or the embolus lamella (L of Figs. 45, 54). There is no way at present to determine the homology. Here it is called the “lamella” (in keys and descriptions).

None of the *Metazygia* species has a paramedian apophysis. As in *Eustala*, the median apophysis has moved ventrally to the side of the palpus (M in Figs. 44, 45, 112, 113) and has lost its sclerotization, often becoming soft and white. The conductor (C) has moved in the same direction, and there is no projection from the conductor toward the cymbium, as in *Alpaida*, to form a paramedian apophysis.

The position of the conductor in araneids may be on the rim of the tegulum, visible in ventral view as in *Neoscona* (Levi, 1995a, C in figs. 6, 7, 16), in *Dubiepeira* (Levi, 1991a, center of fig. 525, C in fig. 526), and in many species of *Araneus* (Levi, 1991a, figs. 3, 14, the light, round sclerite in center of fig. 22), or it may be on the inside face of the tegulum, closer to the cymbium, as in most species with a paramedian apophysis. In the latter case, it is also surrounded on the outside by the wall of the tegulum, as in *Micrathaena* (Levi, 1985, C in figs. 6, 9), *Alpaida* (Levi, 1988, C in fig. 10), and *Wagneriana* (Levi, 1991b, fig. 19). In *Metazygia*, which lack a paramedian apophysis, the conductor may be on the rim, as in *M. creui* (C in Fig. 113) and *M. isabelae* (at 8 hr in Fig. 92), or inside, below the rim of the tegulum, as in *M. castaneoscutata* (center of Fig. 308), or below the rim but hanging over it, as in *M. zilloides* (C in Figs. 44, 45) and *M. gregalis* (at 10 hr in Fig. 259, C in Fig. 260).

In addition to the blister-shaped subterminal apophysis and the lateral position of the median apophysis, there are additional peculiarities in the palpus of the larger species. The radix is pushed “down,” out of the way, and is in a much “lower” position (R in Figs. 44, 45, 112) than in species of other genera. Also, there is a stipes (I) in the form of a band that overlaps the dorsal surface of the palpal bulb (bottom third of Fig. 46), to which the embolus and its lamella are attached (bottom left of Fig. 46, and also Fig. 112). Finally, the median apophysis may be in a more common position (at 5 hr in Fig. 243; M in Fig. 245), the radix farther “up” in the palpus (below the embolus in Fig. 308).

There are many small species in *Metazygia*. As is common in spiders, the smallest species display the greatest diversity in genitalia. Great diversity in genitalia is also known for *Micrathaena* species, mostly medium-sized. Matching males with females of the same species is difficult because so many species are similar in appearance, differing only in genitalic structures.

It has not been possible to clearly group *Metazygia* species into subgenera because the diversity of characters does not fall into correlative patterns. The larger species have a pattern of brackets on the abdomen (Fig. 5), have a terminal apophysis in the palpus (A in Fig. 45), and have the median apophysis (M in Figs. 44, 45) soft and toward the side. Small species have a black band around the anterior of the abdomen (Figs. 381, 404), a diversity of female epigyna, have the male palpus without terminal apophysis, and the median apophysis in the more common araneid position at 4–5 hr in the left palpus (Figs. 383, 389). However, the *Metazygia curari* female (Figs. 144–146) has the characteristic flattened, round scape, as does *M. wittfeldi* (Figs. 1–4), and the male lacks a terminal
apophysis (Fig. 148). Metazygia mundulella also has this kind of scape (Figs. 231–234), but the male has a median apophysis with sclerotized points at 5 hr in the left palpus (Fig. 237). Metazygia serian (Fig. 175) and M. adisi (Fig. 141), with a flattened round “Metazygia” scape, have the black band of small species around the anterior of the abdomen.

Natural History. All species build a vertical orb and have a retreat that is usually above the web and attached to a branch, wall, ceiling, or curled leaf. The spider rests in the retreat during the day and in the center of the web at night. Some webs have a vacant sector in the part of the orb adjacent to the retreat (Plate 1): the vacant sector orb is known for M. wittfeldiae, zilloides, keyserlingi, chicanna, and incerta. The webs of M. keyserlingi and M. laticeps are kept up during the day and have a signal line (Eberhard, personal communication). “All other species built at night, many (all?) quite early in the evening and not generally have either an open sector or a recognizable retreat” (Eberhard, personal communication). Metazygia incerta rebuilds orbs every two to four days (Buskirk, personal communication). Some species take down their webs during the day (Lubin, 1978).

While Metazygia wittfeldiae is usually solitary, the web size and structure are the same when they aggregate and the angle of the orb continues to vary from just horizontal to vertical at Monteverde, Costa Rica (Buskirk 1986).

Eberhard (personal correspondence) writes,

I have watched both gregalis and octama build in great hurry (rapidly, with little exploratory behavior) just as the light is failing, and have web photos of chenevo . . . at 6 pm; serian at 5 pm, lopez at 7 pm; wittfeldiae here [Costa Rica] also builds early in the evening. Thus I suspect these species are working on the flush of insects which fly just at dusk. One keyserlingi also had a web up at night and since I saw another web of this species which was rebuilt around noon after rain, I suspect it is like gregalis in having not one but a series of webs during each 24 hour period. . . .

Species occur often in great abundance, females and males together. But because they are difficult to collect by sweeping or beating, many species are present in collections only as single individuals.

The following observations are excerpted from Eberhard (personal communication):

Relatively open habitat (rel. early secondary growth, grass): lopez, gregalis, octama, pallidula, wittfeldiae, yobena, benella, lazepa, serian, chenevo. I suspect some species at least of preferring to be near water (esp. pallidula), and of liking twigs, barbed wire or other relatively rigid supports for their webs, but have seen yobena and chenevo on webs in tall grass. On buildings (especially near lights): wittfeldiae, gregalis, dubia. Silk retreats, more or less cylindrical (open at both ends—spider will leave on rear if bothered from front side) during the day: octama, gregalis, (in this case, often in cracks or other protected sides); the retreat of this species generally has no connection whatsoever with the web, which is often left intact during the day when the spider is in its retreat, and it is thus generally impossible to associate a given spider with the vestiges of a given web during the day. In contrast, octama removes the web completely during the day, I think usually without a single line being left up, and its retreat is at least sometimes on a green leaf in relatively exposed posi-

Plate 1. A, Metazygia chicanna n. sp. B, M. dubia (Keyserling). C, photograph of web of M. crewi (Banks); horizontal diameter 6 cm. D, photograph of web of M. keyserlingi Banks, horizontal diameter in middle about 12 cm.
tion. I don’t know much about the retreats of the other nocturnal species (and since retreats may be disassociated from webs, I was unlikely to be aware of the spider’s retreat when I found the spider on a web at night).

Dynamics of webs: I can only give you details for gregalis and octama. The octama web seems relatively fragile, and the spiders had often torn down the web and were feeding on a ball of prey not more than a couple of hours after dusk. I never saw one of these (they lived in our yard in Cali) put up another web, but might have missed it (especially if a second web was put up just before dawn and then soon torn down). I had some students do all night projects with gregalis, and they found that the same individual built two to three webs per night. Generally the first web was just at dusk, and the others substantially later at night.

M. gregalis is a generalist when it comes to feeding. I have the impression that intraspecific variation in the form in the Metazygia orb is relatively high in M. gregalis.

Sizes of prey items are reported in Castillo and Eberhard (1983).

Distribution. Metazygia is known only from the Americas. There are several pairs of very similar allopatric species, one north, the other south, without overlap: wittfeldiae and dubia, and ziloides and keyserlingi.

Metazygia species of the southeastern United States, not otherwise cited in this paper, are as follows: M. carolinalis (Arch- er) (the male is unknown); and M. calix (Walckenaer). NEW COMBINATION. Metazygia calix (Levi, 1976, figs. 137-144) was placed in Alpaida but has genitalia similar to those of M. laticeps (Figs. 226, 227, 230) and M. sendero (Figs. 216, 217, 221).

Misplaced Species. Metazygia livida Mello-Leitão, 1941: 151, 17. Female from Argentina is a Dictyna (Dictynidae).

Keys. Keys are difficult to construct for species of which only one or a few individuals are known. With few specimens, one does not know whether or not the coloration is characteristic, whether or not the epigynum has been torn apart by a male when mating, whether the male has a virgin embolus with a cap or if he has mated, and whether all males of the species have a macroseta on the fourth coxa or only the one sampled.

For using the key, the female’s epigynum has to be slightly pulled out with a curved needle to see the posterior face of the structure.

**Key to Female Metazygia**

- Fourth coxae without macroseta or tubercle 15
5(4). Fourth coxae with a tubercle; embolus of palpus thorn-like (Fig. 357, E in Fig. 359); Venezuela, Amazon area (Map 4D) — lopez
— Fourth coxae with macroseta — 6

5(6). Carapace with a lobe above first coxae (Fig. 390) 7
— Carapace without lobe above first coxae — 13

7(6). Abdomen posteriorly black (Fig. 388); Mato Grosso, Brazil (Map 4E) — voxanta
— Abdomen posteriorly light — 8

8(7). In mesal view, median apophysis projecting beyond tegulum (at 3 hr in Fig. 318, at 3 hr in Fig. 423) — 9
— Median apophysis smaller and not projecting beyond tegulum (Figs. 313, 383, 418, 425) — 10

9(8). Median apophysis very large, facing cymbium at 3 hr in Figure 423; Bahia, Brazil (Map 4H) — atama
— Median apophysis distally rectangular in mesal view at 3 hr in Figure 318; Amazon area (Map 4C) — mariahelenae

10(8). Embolus S-shaped as seen through transparent lamella (between 11 hr and at center in Fig. 313) — octama
— Embolus otherwise, usually hidden (Figs. 383, 418, 425) — 11

11(10). Median apophysis with bulge on side (at 3 hr in Fig. 425, right of center in Fig. 426); coastal Ecuador (Map 4I) — oro
— Median apophysis without bulge (Figs. 383, 418) — 12

12(11). Median apophysis subtriangular (at 3 hr in Fig. 418); Rio Grande do Sul, Brazil (Map 4H) — cunha
— Median apophysis distally enlarged (at 4 hr in Fig. 383); Peruvian Amazon (Map 4E) — genaro

13(6). Embolus a thread with a transverse loop as in Figures 112 and 113; Greater Antilles (Map 21) — crewi
— Embolus otherwise (Figs. 327, 332) — 14

14(13). Median apophysis distally tapering to a point (at 3 hr in Fig. 327); Mexico, Central America (Map 4G) — nigrocincta
— Median apophysis distally bulging as in 4 hr in Figure 352; southern Amazon region to Misiones Prov., Argentina (Map 4C) — lagiana

15(4). Carapace with small lobe above first coxa (Figs. 376, 415, 421) — 16
— Carapace without lobe — 18

16(15). Abdomen with ventral black band as in Figure 377; Peru (Map 4E) — manu
— Abdomen marked otherwise — 17

17(16). Sickle-shaped embolus (Fig. 414); Colombian Amazon (Map 4F) — rothi
— Embolus barely visible, hidden by large sclerotized lamella (at 11 hr in Fig. 420); eastern Pará State, Brazil (Map 4I) — aldela

18(15). Abdomen with median, transverse light band (Fig. 417); palpus as in Figure 416; Amazon area (Map 4I) — cazaena
— Abdomen and palpus otherwise — 19

19(18). Palpus with terminal apophysis (A in Figs. 45, 112, top of Figs. 162, 201, 207) — 20
— Palpus without terminal apophysis, only a lamella (Figs. 142, 148, 213, 221, 225, 230, 237, 243-246) — 38

20(19). Terminal apophysis with distal straight or slightly curved prong (Figs. 6, 13) — 21
— Terminal apophysis with short distal prong (between center and 2 hr in Fig. 91); Mato Grosso, Brazil (Map 2C) — isabelae

21(20). In mesal view terminal apophysis with two prongs (between center and 2 hr in Fig. 6); southern United States to Costa Rica (Map 2A) — wittfeldiae
— Terminal apophysis otherwise (Figs. 13, 27) — 22

22(21). A comb projecting beyond prong in mesal view (at 1 hr in Figs. 20, 27, 66) — 23
— No comb-like projection (Figs. 13, 201) — 25

23(22). Comb-like projection longer than wide in mesal view (at 1 hr in Fig. 20); tegulum with pointed spine (at 3 hr in Fig. 21); Costa Rica to Guianas and northern Peru, Galapagos Islands and West Indies (Map 2A) — dubia
— Comb-like projection in mesal view wider than long (at 1 hr in Figs. 27, 66); tegulum without pointed spine (Figs. 28, 67) — 24

24(23). Comb small (at 1 hr in Fig. 66), most of embolus hidden behind conductor (Figs. 66, 67); northern Peruvian Amazon (Map 2B) — pastaza
— Comb large (at 1 hr in Fig. 27), most of embolus exposed, only tip of conductor hidden (at 3 hr in Fig. 27); Venezuela to Peruvian coast (Map 2D) — pimentel

25(22). A pointed tooth projecting beyond prong of terminal apophysis in mesal view (at 1 hr in Fig. 13, center in Fig. 14); Bahama Islands (Map 2A) — bahama
— No such tooth — 26

26(25). Medial apophysis projecting beyond other sclerites toward 4 hr, conductor toward 3 hr with triangular space between these sclerites in mesal view (Figs. 201, 207); southern Brazil — 27
— Median apophysis and conductor otherwise (Figs. 60, 99, 104, 213) — 28

27(26). Conductor with a knob at tip (at 3 hr in Fig. 201); median apophysis straight
(at 4 hr in Fig. 201); Rio Grande do Sul, Brazil (Map 3A) ________ saturnino

Conductor tapering to tip (at 3 hr in Fig. 207); median apophysis with elbow (at 4 hr in Fig. 207); southeastern Brazil (Map 3B) ___________ crabroniphila

28(26). Tip of embolus with horseshoe-shaped structure (Fig. 104, center of Fig. 105); Guianas, Amazon area (Map 2F) ________ jamari

- Tip of embolus otherwise, or hidden by conductor (Figs. 60, 99, 162) ___________ 29

29(28). Embolus long, saber-shaped, and curved up (Fig. 99); southeastern Brazil (Map 2C) ___________ rogenhoferi

- Embolus otherwise (Figs. 73, 119, 162) ___________ 30

30(29). Embolus U-shaped (with dark cap as in Fig. 119); Guatemala (Map 2I) ________ carrizal

- Embolus otherwise ___________ 31

31(30). Embolus a small hook as in center of Figure 162; western Amazon area (Map 2K) ___________ yucumo

- Embolus otherwise ___________ 32

32(31). Embolus almost straight structure, tip hidden by terminal apophysis protruding as in Figure 85; Neblina area of Amazon (Map 2E) ___________ enabla

- Embolus otherwise ___________ 33

33(32). Embolus thorn-shaped as in Figure 33; Peruvian Amazon to Bahia, Brazil (Map 2D) ___________ patiana

- Embolus otherwise; Mexico, Central America ___________ 34

34(33). Embolus lamella (L in Figs. 45, 54) covering most of embolus with one large point and a forked tooth as in Figure 73; Central America (Map 2J) ________ incerta

- Embolus lamella otherwise (Figs. 44, 54, 60, 79) ___________ 35

35(34). Embolus lamella triangular tip covered by blister-like part of terminal apophysis (center in Fig. 60); southern Mexico to Honduras, Jamaica (Map 2B) ___________ chicanna

- Embolus lamella otherwise ___________ 36

36(35). Embolus lamella rounded as in Figure 44; Florida, Texas to Honduras, Cuba, Jamaica (Map 2G) ___________ zilloides

- Embolus lamella otherwise ___________ 37

37(36). Embolus lamella with axis of tip at right angle to axis of cymbium (Fig. 54); embolus without lobes (Fig. 54); Costa Rica to Trinidad and Colombia (Map 2G) ___________ keyserlingi

- Embolus lamella with tip pointing toward 1 hr in Figure 79; embolus with two lobes below (Figs. 79, 80); Mexico to Guianas and Peru (Map 2E) ___________ pallidula

38(19). Median apophysis long, thumb-shaped and projecting beyond tegulum (at 3 hr in Figs. 302, 308) ___________ 39

39(38). Embolus lamella projecting beyond cymbium edge as at 11 hr in Figure 308; Amazon area (Map 4B) ___________ castancoscutata

- Cymbium edge extending beyond lamella as at 11 hr in Figure 302; Amazon area (Map 4A) ________ vaupes

40(39). Tegulum with a large fold having a comb (at 12 hr in Figs. 283, 295) ___________ 41

- Tegulum otherwise ___________ 42

41(40). Embolus axis at right angle to axis of cymbium (Fig. 253); Amazon area to southeastern Brazil (Map 3D) voluptifica

- Embolus axis forming an acute angle with that of cymbium (Fig. 295); Guyana (Map 4A) ________ tanica

42(41). Tegulum with a large distal lobe (at 12 hr in Figs. 237, 237) ___________ 43

- Tegulum otherwise or only small lobe ... 44

43(42). Lamella with subparallel sides distally concave (at 3 hr in Fig. 248, at 10 hr in Fig. 248, L in Fig. 245); median apophysis with one point (at 5 hr in Fig. 243, M in Fig. 245); Bahia State to Rio Grande do Sul, Brazil (Map 3F) ___________ genialis

- Lamella distally narrowing (at 3 hr in Fig. 237); median apophysis with two points (at 5 hr in Fig. 237); southeastern Brazil (Map 3F) ___________ mundella

44(43). Median apophysis "hanging down"; up-side-down T-shaped (at 6 hr in Fig. 250); Guianas (Map 3D) ___________ ikuruwa

- Median apophysis otherwise (Figs. 142, 149, 213, 213, 230) ___________ 45

45(44). Lower edge of median apophysis semi-circular (at 5 hr in Figs. 213, 230) ___________ 46

- Median apophysis otherwise (Figs. 142, 148, 221, 225) ___________ 47

46(45). Palpus as in Figure 230; Panama to Rio de Janeiro State, Brazil (Map 3F) ___________ laticeps

- Palpus as in Figure 213; Bolivia to Mato Grosso do Sul (Map 3B) ___________ corumba

47(45). Embolus thread-like curving "above" tegulum (at 12 hr in Fig. 142); Neblina area of Amazon (Map 2H) ________ arnoi

- Embolus otherwise (Figs. 148, 221, 225) ___________ 48

48(47). Median apophysis having a "bottom" bulge and tip hidden by conductor in mesal view (Figs. 148, 149); Amazon area (Map 2H) ___________ curari

- Median apophysis otherwise (Figs. 221, 225) ___________ 49

49(48). Median apophysis as in Figure 225; Amazon area (Map 3B) ________ uma

- Median apophysis as in Figure 221; Ecuador to Amazonian Peru (Map 3B) ___________ sendero
**Metazygia wittfeldae** (McCook)  
Figures 1–7; Map 2A

*Epeira wittfeldae* McCook, 1894: 168, pl. 7, figs. 6, 7, 9, 10. Three female, two male, and one imm. male syntypes from Florida in ANSP, examined.  

**Description.** Female from Tabasco, Mexico. Carapace orange, cephalic region dark orange. Chelicerae dark orange. Labium, endites, sternum orange. Coxae, legs orange. Dorsum of abdomen with gray pattern on white pigment spots (Fig. 5); venter light orange-gray, without marks. Posterior median eyes 0.5 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of eylepus equals 0.5 diameter of anterior median eye. Total length 8.0 mm. Carapace 4.2 mm long, 3.1 wide, 1.9 behind lateral eyes. First femur 3.2 mm, patella and tibia 4.1, metatarsus 3.0, tarsus 1.2. Second patella and tibia 3.8 mm, third 2.3, fourth 3.1.

Male from Tabasco, Mexico. Color as in female but cephalic region lighter. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 1 diameter from laterals. Posterior median eyes 0.3 diameter apart, 2.1 diameters from laterals. Height of eylepus equals 0.5 diameter of anterior median eye. Second tibia thicker than first, both first and second with macrosetae. Total length 5.2 mm. Carapace 2.9 mm long, 2.1 wide, 1.1 behind lateral eyes. First femur 2.7 mm, patella and tibia 3.5, metatarsus 3.0, tarsus 1.1. Second patella and tibia 3.1 mm, third 1.7, fourth 2.1.

**Note.** Males and females are commonly collected together.

**Variation.** Total length of females 7.2 to 11.1 mm, males 4.2 to 7.2. Illustrations were made from specimens from Tabasco State, Mexico.

**Diagnosis.** In ventral view the epigynum is twice as wide as long and has posterior swellings on each side (Fig. 2); in related species *M. dubia* (Fig. 16) and *M. bahama* (Fig. 9), it is narrower and lacks these swellings. Males are separated from *M. dubia* and *M. bahama* by the soft prong parallel to the sclerotized prong of the terminal apophysis (at 1 hr in Fig. 6), which is absent in the other two. The distribution of *M. wittfeldae* is allopatric with respect to related species (Map 2A).

**Natural History.** Specimens were collected under eaves of buildings and in brush and are commonly found in mud-dauber wasp nests.

**Specimens Examined.** MEXICO Tamaulipas: Ciudad Mante (AMNH); Tampico (AMNH). *San Luis Potosí*: Tamazunchale (AMNH, CAS); Valles (AMNH). Zacatecas: Tabasco (MCZ). Nayarit: Tepic (AMNH); 27 km S Acaponeta (CAS). Colima: Santiago, NW Manzanillo (AMNH). Veracruz: Acayucan (CAS); Catemaco (AMNH, CAS); 7.5 km W Catemaco; 17 km W Cerro Azul; Córdoba; Fortín de las Flores; Jalapa; La Palma; Lago Catemaca (all AMNH); Tamaulipas: Ciaochon (CAS); Papantla; Tectoluta (all AMNH); Veracruz (AMNH, MCZ); Orizaba (MCZ). Guerrero: 13 km W Acapulco (AMNH). Oaxaca: Tehuantepec; 3.2 km NE Tehuantepec (all AMNH). Tabasco: Villa Hermosa (AMNH). Tucatan: Chetumal (MCZ). Chiapas: Palenque Ruins (MCZ); Prusia (AMNH). BELIZE: Stann Creek: Dungria (MCZ); 80 km S Stann Creek (MCZ); Twin Cays, W of Swamp Dock (USNM). GUATEMALA: Antigua; Moca; Suchitepequez; San Julian; Tiziquate; Variedades; Zacapa (all AMNH). HONDURAS: Lancetilla, nr. E Tela (MCZ). NICARAGUA: Lago Jilóí (SR). COSTA RICA: Cartago: Turrialba (MCZ). Guanacaste: 4 km NW Cañas (MCZ); nr. Cañas (MCZ). San José: San José, common in city (AMNH, MCZ).

**Metazygia bahama new species**  
Figures 8–14; Map 2A

**Holotype.** Male holotype, one male, two female paratypes from South Bimini, Bahama Islands, June 1951 (M. A. Cazier), in AMNH. The specific name is a noun in apposition after the type locality.

**Description.** Female paratype. Carapace orange-brown with sides of thoracic
region orange. Chelicerae red-brown. Labium, endites dark orange. Sternum, coxae, legs orange. Dorsum of abdomen with pairs of black brackets (Fig. 12); venter light gray without marks. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 2 diameters from laterals. Posterior median eyes 0.3 diameter apart, 4 diameters from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. Total length 8.0 mm. Carapace 3.9 mm long, 2.7 wide, 1.7 behind lateral eyes. First femur 2.9 mm, patella and tibia 3.7, metatarsus 2.5, tarsus 1.1. Second patella and tibia 3.4 mm, third 2.1, fourth 2.7.

Male holotype. Color as in female. Posterior median eyes 0.6 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.3 diameter apart, 2.2 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Second tibia slightly thicker than first, with stronger macrosetae. Abdomen widest in middle. Total length 5.1 mm. Carapace 2.8 mm long, 2.1 wide, 1.1 behind lateral eyes. First femur 2.8 mm, patella and tibia 3.7, metatarsus 2.8, tarsus 1.1. Second patella and tibia 3.1 mm, third 1.7, fourth 2.2.

Note. Males and females were collected together.

Variation. Total length of females 6.7 to 10.7 mm, males 4.8 to 5.7. Illustrations were made from the male holotype and a female paratype collected with it.

Diagnosis. Epigynum of the female (Fig. 9) is narrower than that of M. wittfeldiae in ventral view (Fig. 2), and the posterior median plate is wider dorsally (at 6 hr in Fig. 10) than that of M. dubia (at 6 hr in Fig. 17) in posterior view. The male differs from both of these species by having a spine on the subterminal apophysis (at 1 hr in Fig. 13 and center of Fig. 14).

Natural History. This species probably has habits similar to M. wittfeldiae and M. dubia.

Distribution. Bahama Islands. The distribution does not overlap that of M. dubia and M. wittfeldiae (Map 2A).

Paratypes. From type locality: June 1950, 6♀, 1♂, imm. (M. A. Cazier, F. Rindge, AMNH); May 1951, 5♀, 4♂, imm. (M. Cazier, W. J. Gertsch, AMNH); June 1951, 3♀, 1♂, imm. (M. A. Cazier; C., P. Vaurie, AMNH); July 1951, 1♂ (C., P. Vaurie, AMNH).

Specimen Examined. BAHAMA ISLANDS Dog Key, N Andros Island, 13 May 1904, 1♂ (AMNH).

Metazygia dubia (Keyserling)
Plate 1; Figures 15–21; Map 2A

Epeira dubia Keyserling, 1864: 123, pl. 4, figs. 12, 13,♀. Two female syntypes from Sta. Fé de Bogotá, N. Granada [Bogotá, Colombia], in BMNH, examined. Keyserling, 1892: 187, pl. 9, fig. 138,♀.

Epeira moraballicus Moraballi, 1932: 363, figs. 53, 54, web. Specimens from the Essiquibo River, Guyana, lost [not in BMNH]. NEW SYNONYMY.

Aranaea dubia:—Roewer, 1942: 841.
A. moraballicus:—Roewer, 1942: 847.
Araneus moraballicus Bonnet, 1955: 546.

Synonymy. Hingston’s E. moraballicus is synonymized with M. dubia because Hingston described the proximity of the posterior median eyes, the oval abdomen, and the Zygiella x-notata–like web. Also, only a few Guianan Metazygia are 11 mm total length. (The other large Metazygia, M. laticeps, has spinnerets anterior of the posterior tip, a fact noticed by Hingston for his Epeira folisecens, but not here.)

Figures 1–7. Metazygia wittfeldiae (McCook), 1–5, female. 1–4, epigynum. 1, anterior. 2, ventral. 3, posterior. 4, lateral. 5, dorsal. 6, 7, left male palpus. 6, mesal. 7, apical.

Figures 8–14. M. bahama n. sp. 8–12, female. 8–11, epigynum. 8, anterior. 9, ventral. 10, posterior. 11, lateral. 12, dorsal. 13, 14, male palpus. 13, mesal. 14, apical.
Figures 15–21. *M. dubia* (Keyserling). 15–19, female. 15–18, epigynum. 15, anterior. 16, ventral. 17, posterior. 18, lateral. 19, dorsal. 20, 21, male palpus. 20, mesal. 21, apical.

Figures 22–28. *M. pimentelii* n. sp. 22–26, female. 22–24, epigynum. 22, ventral. 23, posterior. 24, lateral. 25, dorsal. 26, abdomen, ventral. 27, 28, male palpus. 27, mesal. 28, apical.

Scale lines. 1.0 mm, genitalia 0.1 mm.
Bonnet (1955: 466) lists the name *Epeira dubia* erroneously as a synonym of *Araneus cornutus* [= *Larinioides cornutus* (Clerck 1758)].

**Description.** Female from Gamboa, Panama. Carapace brown, sides of thoracic region orange. Chelicerae brown. Labium, endites light brown. Sternum orange. Coxae light orange, legs orange. Dorsum of abdomen whitish with gray marks (Fig. 19); venter light gray without marks. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes their diameter apart, two diameters from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 9.5 mm. Carapace 4.1 mm long, 2.9 wide, 2.2 behind lateral eyes. First femur 3.4 mm, patella and tibia 4.0, metatarsus 3.0, tarsus 1.2. Second patella and tibia 3.8 mm, third 2.1, fourth 3.3.

Male from Gamboa. Color as in female, but carapace all orange. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes their diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 6.7 mm. Carapace 3.5 mm long, 2.5 wide, 1.5 behind lateral eyes. First femur 3.5 mm, patella and tibia 4.4, metatarsus 3.7, tarsus 1.4. Second patella and tibia 3.8 mm, third 2.1, fourth 2.7.

**Note.** Males and females were collected together.

**Variation.** Total length of females 7.2 to 11.7 mm, males 4.8 to 6.2. The abdomen may have dark marks or sometimes none at all. The scape is torn off the epigynum in some females. The epigynum of a female from Depto. Huila, Colombia, is heavily sclerotized. A male from Venezuela had the tegulum spine short. Illustrations were made from a female and male from Gamboa, Panama; the specimen on Plate 1 is from Negril, Jamaica.

**Diagnosis.** The *Metazygia dubia* epigynum (Fig. 16) is narrower in ventral view than that of *M. wittfeldiae* (Fig. 2) and lacks the swelling on each side. It has a narrower scape (Figs. 16, 17) than that of *M. bahama* (Figs. 9, 10). Males can be separated from the more northern *M. wittfeldiae* by the distal comb-like projection of the male terminal apophysis (at 1 hr in Fig. 20, center of Fig. 21) and by the long black spine on the tegulum (at 3 hr in Fig. 21).

**Natural History.** This species was collected from disturbed areas outside and sometimes inside buildings. It was found under bark in Cuba and was collected from coral just above the high tide mark in Jamaica; from pasture and from dense vegetation in Jamaica; on a wire fence at Coamo, Puerto Rico; and under a roof overhang and on a boat dock on Barro Colorado Island, Panama. Specimens from Galapagos were found in seashore vegetation. The spiders are nocturnal and sit in a silk retreat during the day. There is no signal line to the retreat. The vertical web is rebuilt every evening and has a partly closed hub (Lubin, personal communication). Some specimens come from mud-dauber wasp nests.

**Distribution.** Costa Rica, West Indies to Brazil and Peru and Galapagos Islands. It does not overlap *M. wittfeldiae* (Map 2A).

**Metazygia pimentel** new species

**Figures 22–28; Map 2D**

**Holotype.** Male holotype and four female paratypes from Pimentel, Depto. Lambayeque, Peru, 21 Sept. 1988 (D. Silva D.), in MUSM; one paratype in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female paratype. Carapace orange, darkest in eye region. Chelicerae dark orange-brown Labium, endites, sternum light orange. Coxae light orange, legs orange. Dorsum of abdomen whitish with five pairs of black spots (Fig. 25); venter with indistinct white patch surrounded by dusky area (Fig. 26). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 2.2 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.7 diameter of anterior median eye. Total length 8.2 mm. Carapace 4.5 mm long, 3.4 wide, 2.1 behind lateral eyes. First femur 3.4 mm, patella and tibia 4.1, metatarsus 2.7, tarsus 1.2. Second patella and tibia 3.8 mm, third 2.5, fourth 3.4.

Male holotype. Color as in female but white patch in dusky area on venter of abdomen is more distinct. Posterior median eyes 0.7 diameter of anterior medians, anterior laterals 0.7 diameter, posterior laterals 0.6. Anterior median eyes 0.4 diameter apart, 1.2 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 5.7 mm. Carapace 3.1 mm long, 2.4 wide, 1.4 behind lateral eyes. First femur 2.9 mm, patella and tibia 3.7, metatarsus 2.7, tarsus 1.2. Second patella and tibia 3.0 mm, third 1.9, fourth 2.3.

**Note.** Males and females were collected together.

**Variation.** Total length of males 5.7 to 6.3. Illustrations were made from the type specimens.

**Diagnosis.** The median, less sclerotized triangular area of the epigynum is more pointed (Fig. 22) than that of *M. dubia* (Fig. 16). The male has a comb-like projection of the subterminal apophysis (at 1 hr in Fig. 27) but lacks the spine on the tegulum that is present in *M. dubia* (at 3 hr in Fig. 21). The venter of the abdomen has a white patch (Fig. 26) absent in similar species.

**Natural History.** Specimens were abundant in branches of locust “algarobos,” *Prosopis*, a leguminous tree growing in sand dunes in Peru, and dry to very dry tropical forest in Venezuela.

**Distribution.** Venezuela, Peru in arid areas (Map 2D).

**Metazygia patiama** new species

**Figures 29–34; Map 2D**

**Holotype.** Female holotype from Fazenda Matiapá, Camacan, Bahia, Brazil, 16 Oct. 1978 (J. S. Santos), in MCN no. 11116; male paratype, same locality and collector, 14 Oct. 1978, in MCN no. 10182. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange. Chelicerae orange-brown. Labium, endites dark orange. Sternum orange. Coxae light orange; legs dark orange, distal parts of articles darker. Dorsum of abdomen setose, with anterior pair of dark patches on dusky white and posterior quarter dark gray (Fig. 32). Venter black, fading toward sides. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 1.2 diameters from laterals. Posterior median eyes 0.2 diameter apart, 2.4 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 5.6 mm. Carapace 2.8 mm long, 2.2 wide, 1.4 behind lateral eyes. First femur 2.5 mm, patella
and tibia 2.7, metatarsus 1.9, tarsus 0.9. Second patella and tibia 2.6 mm, third 1.6, fourth 2.3.

Male paratype. Color light orange, except for abdomen, which has tiny white pigment spots dorsally and lacks all gray or black marks. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.8 diameter apart, 0.8 diameters from laterals. Posterior median eyes 0.2 diameter apart, 1.3 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.4 mm. Carapace 2.3 mm long, 1.6 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.5, metatarsus 1.7, tarsus 0.7. Second patella and tibia 2.3 mm, third 1.3, fourth 1.6.

Note. Males and females were collected at the same locality.

Variation. Total length of females 5.6 to 5.7 mm. Illustrations were made from the type specimens.

Diagnosis. The epigynum (Fig. 29) is wider than that of *M. pimentel* in ventral view (Fig. 22), and in posterior view (Fig. 30) the lateral plates appear wider than those of *M. pimentel* (Fig. 23) and *M. dubia* (Fig. 17). The male palpus (Figs. 33, 34) lacks the comb-like projection of the terminal or subterminal apophysis found in *M. dubia* (at 1 hr in Fig. 20) and *M. pimentel* (at 1 hr in Fig. 28) and also lacks the spine on the tegulum. The pattern on the abdomen (Fig. 32) is not a complete folium as in related species.

Natural History. Specimens were collected at night in Peru.

Distribution. Amazon region of Peru to Bahia State, Brazil (Map 2D).

*Specimen Examined. PERU Madre de Dios: Zona Reservada de Manu, Puesto de Vigilancia Pakitza, 6 Oct. 1987, D. Silva D., J. Coddington, USNM.*

**Metazygia ipago new species**

Figures 35–38; Map 2D

Holotype. Female holotype from Igarapeçu, igapó capim flutuante (periodically flooded forest), Est. Pernambuco, Brazil. 12 July 1980, in MNRJ. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange, cephalic region dark orange. Chelicerae dark orange. Labium, endites dark orange. Sternum orange. Coxae light orange, legs orange. Dorsum of abdomen with a faint gray folium on white (Fig. 38); venter with some white pigment spots on light gray behind epigynum. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 1.2 diameters from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 6.8 mm. Carapace 3.4 mm long, 2.7 wide, 1.5 behind lateral eyes. First femur 3.1 mm, patella and tibia 4.0, metatarsus 2.7, tarsus 1.1. Second patella and tibia 3.5 mm, third 1.9, fourth 2.7.

Diagnosis. In ventral view there is a groove to each side of the median area of the epigynum (Fig. 35). The groove is absent in the epigynum of *M. patiama* (Fig. 29) and similar species.

**Metazygia zilloides** (Banks)

Figures 39–47; Map 2G

*Epeira zilloides* Banks, 1898: 255, pl. 15, fig. 2, 4, 6.

Three female, one male, and one juvenile syntype from Tepic, Nayarit, Mexico, in MCZ, examined.

**Aranea dilatata** F. P.-Cambridge, 1904: 513, pl. 49,

Abbreviations. A, terminal apophysis; B, blister-like subterminal apophysis; C, conductor; E, embolus; H, hematodocha; I, stipes; L, embolus lamella; M, median apophysis; P, paracymbium; R, radix; Y, cymbium.

Scale lines. 1.0 mm, genitalia 0.1 mm.
Description. Nontype female from Tepic, Nayarit, Mexico. Carapace orange, dusky in midline. Chelicerae, labium orange-brown. Endites, sternum orange, sides darker. Coxae, legs orange, distal ends of femora and tibiae darker. Dorsum of abdomen with white pigment spots and anterior black marks (Fig. 43); venter with white pigment spots. Eyes subequal. Anterior median eyes 0.8 diameter apart, 1.2 diameters from laterals. Posterior median eyes 0.3 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 7.4 mm. Carapace 3.0 mm long, 2.6 wide, 1.3 behind lateral eyes. First femur 3.6 mm, patella and tibia 4.6, metatarsus 3.1, tarsus 1.1. Second patella and tibia 3.7 mm, third 2.1, fourth 3.0.

Male from Tepic, Mexico. Color as in female, but abdomen darker with posterior transverse bars, and venter with a transverse white patch behind genital groove, which is surrounded by black. Posterior median eyes same diameter as anterior medians, laterals 0.9 diameter. Anterior median eyes 0.9 diameter apart, 1 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.8 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.8 mm. Carapace 2.6 mm long, 2.1 wide, 1.0 behind lateral eyes. First femur 3.2 mm, patella and tibia 4.5, metatarsus 3.6, tarsus 1.1. Second patella and tibia 3.4 mm, third 1.7, fourth 2.4.

Note. Males and females were collected together.

Variation. Total length of females 3.8 to 6.7 mm, males 3.0 to 5.0. Illustrations were made from nontype specimens from Tepic, Mexico.

Diagnosis. Females are difficult to separate from M. keyserlingi. The embolus part stuck in the opening is smaller (Fig. 40), and there is a median ventral groove in posterior view of the epigynum (arrow in Fig. 41). The male differs from that of M. keyserlingi (Fig. 54) by the round shape of the embolus lamella (L in Fig. 44).

Natural History. Specimens were collected in second-growth forest edge in Mexico and from beach grape, in a hotel, and in a citrus orchard and pasture in Jamaica. Others came from a Sceliphron wasp nest in Jamaica.

Specimens Examined. MEXICO Tamaulipas: Limón (AMNH); Mante (AMNH). Nuevo León: Linares (AMNH); Los Cristales (AMNH), San Luis Potosí: Tamazunchale (AMNH); Valles (AMNH). Nayarit: 3 km N Compostela (AMNH); Tepic (AMNH). Jalisco: Chapala (CAS); Puerto Vallarta (AMNH); Tizapán (AMNH). **Metazygia keyserlingi** Banks

**Plate 1; Figures 48–54; Map 2G**

**Synonymy.** Banks designated two vials with females as types, two females collected on 20–24 June and three females on 13 July (both without year). This species had been erroneously synonymized with *M. zilloides* (Levi, 1977). When describing *M. keyserlingi*, Banks compared it to *M. pallidula* but not to his own *M. zilloides*, which is more similar to *M. keyserlingi* than is *M. pallidula*.

**Description.** Female from Barro Colorado Island. Carapace orange. Chelicerae, labium, endites orange. Sternum orange. Legs orange. Dorsum of abdomen whitish with two indistinct black longitudinal bands (Fig. 52). Venter with some white pigment behind epigynum, dark dusky on each side between epigynum and spinnerets, and with a faint white line on each side (Fig. 53). Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.3 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.5 mm. Carapace 1.9 mm long, 1.5 wide, 0.9 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.5, metatarsus 1.7, tarsus 0.7. Second patella and tibia 1.9 mm, third 1.1, fourth 1.7.

Male from Barro Colorado Island. Color as in female. Eyes subequal. Anterior median eyes 1.2 diameters apart, 1 diameter from laterals. Posterior median eyes 0.5 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 3.6 mm. Carapace 1.8 mm long, 1.3 wide, 0.7 behind lateral eyes. First femur 2.0 mm, patella and tibia 2.5, metatarsus 2.0, tarsus 0.8. Second patella and tibia 2.0 mm, third 1.0, fourth 1.4.

**Note.** Males and females were collected together.

**Variation.** Total length of females 3.5 to 5.7 mm, males 2.3 to 3.6. Illustrations were made from specimens collected from the type locality: Barro Colorado Island, Gatún Lake, Panama. The web photograph (Pl. 1) is also from Barro Colorado Island, Panama.

**Diagnosis.** The white patch on the venter of the abdomen (Fig. 53) is more discrete and the groove present in *M. zilloides* (arrow in Fig. 41) is smaller or absent (Fig. 50). The male can be told from *M. zilloides* (Fig. 44) by the embolus lamella (L in Fig. 54), which is pointed “above” the embolus. The females are difficult to separate from *M. zilloides*, but all the ones collected with males had the central swollen part of the epigynum 0.32 mm wide, whereas those of *M. zilloides* had the swollen part of the epigynum 0.40 mm wide. The epigynum of *M. keyserlingi* has a slightly smaller scape than that of *M. zilloides*.

**Natural History.** This species was collected in moist tropical forest in Costa Rica, in leaf litter in Panama, and in a garden in Cali, Colombia. Males are uncommon in collections.

**Distribution.** Costa Rica to southern Colombia, Trinidad (Map 2G).

**Metazygia chicanna** new species Plate 1; Figures 55–61; Map 2B

**Holotype.** Female holotype and female and two male paratypes from Chicanna Ruins, 8 km W Xpujil, ca. 19°03′N, 89°51′W, Campeche, Mexico, 12–14 July 1983 (W. Maddison), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange, with median dusky band. Chelicerae, labium, endites, sternum orange. Coxae, legs orange. Dorsum of abdomen with two pairs of black bands, sides black (Fig. 55); venter with a central white patch (Fig. 59). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.6 diameters from laterals. Height of clypeus equals 0.6 diameter of the anterior median eyes. Total length 5.5 mm. Carapace 2.2 mm long, 1.5 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.7, metatarsus 1.8, tarsus 0.7. Second patella and tibia 2.3 mm, third 1.3, fourth 1.9.

Male paratype. Color as in female, but legs indistinctly ringed darker, and abdomen with two pairs of longitudinal bands. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.9 diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.8 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 3.5 mm. Carapace 1.9 mm long, 1.4 wide, 0.7 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.6, metatarsus 2.1, tarsus 0.9. Second patella and tibia 2.1 mm, third 1.1, fourth 1.6.

**Note.** Males and females were collected together.

**Variation.** Total length of females 2.5 to 5.8 mm, males 2.5 to 4.2. Illustrations were made from paratypes; the photograph (Pl. 1) was made in Negril, Jamaica.

**Diagnosis.** All specimens have a white spot on the venter of the abdomen (Fig. 59). Females can be distinguished by the ventral view of the epigynum, which has a cone-shaped scape with openings on each side (Fig. 55). The scape also has a kink in lateral view (Fig. 57). Unlike other species, the male has a cone-shaped embolus lamella (at center of Fig. 60).

**Natural History.** The holotype came from short tropical rain forest. Other specimens came from moist forest border in Quintana Roo, Mexico, border of forest road; from roadside, on top of woody shrubs without leaves; and from beach grape in Jamaica.

**Distribution.** From Yucatan Peninsula, Mexico, to Honduras, Jamaica (Map 2B).

*Scale lines.* 1.0 mm, genitalia 0.1 mm.

**Metazygia tapa** new species

**Figures 62–65; Map 2B**

**Holotype.** Female holotype and two female paratypes from Zona Reservada Tambopata, 290 m, 12°50'S, 69°17'W, 3 June 1988, 1♀ (J. C. Coddington, USNM).

**Metazygia pastaza** new species

**Figures 66–68; Map 2B**

**Holotype.** Male holotype from Pastaza, Depto. Loreto, Prov. Alto Amazonas, Peru, swump plants, Aug. 1973 (J. C. Olin), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Carapace orange, cephalic region darker orange. Chelicerae orange-brown. Labium, endites dark orange. Sternum orange. Coxae, legs orange. Dorsum of abdomen with folium as in related species (Fig. 68); venter with scattered white pigment spots. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.5 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.8 diameters from laterals. Height of Clypeus equals 0.5 diameter of anterior median eye. Total length 5.4 mm. Carapace 2.3 mm long, 1.9 wide, 1.0 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.5, metatarsus 1.6, tarsus 0.8. Second patella and tibia 2.1 mm, third 1.5, fourth 2.0.

**Variation.** Total length of females 4.9 to 6.0 mm. Illustrations were made from the holotype.

**Diagnosis.** The abdomen is oval and slightly pointed anteriorly, widest in middle (Fig. 65). Metazygia tapa is separated from *M. ipago* and *M. patiama* by the dark patches in ventral view of the epigynum (Fig. 62) and the narrow posterior median plate (Fig. 63).

**Natural History.** Specimens were collected by fogging at night in Depto. Loreto, Peru.

**Distribution.** Amazon drainage, Peru (Map 2B).

**Paratype.** PERU Madre de Dios: Zona Reservada Tambopata, 290 m, 12°50'S, 69°17'W, 3 June 1988, 1♀ (J. C. Coddington, USNM).

**Metazygia tapa** new species

**Figures 62–65; Map 2B**

**Holotype.** Female holotype and two female paratypes from Zona Reservada Tambopata, 290 m, 12°50'S, 69°17'W, 3 June 1988, 1♀ (J. C. Coddington, USNM).

**Metazygia pastaza** new species

**Figures 66–68; Map 2B**

**Holotype.** Male holotype from Pastaza, Depto. Loreto, Prov. Alto Amazonas, Peru, swump plants, Aug. 1973 (J. C. Olin), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Carapace orange, cephalic region darker orange. Chelicerae orange-brown. Labium, endites dark orange. Sternum orange. Coxae, legs orange. Dorsum of abdomen with folium as in related species (Fig. 68); venter with scattered white pigment spots. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.5 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.8 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Second tibia as thick as first. Total length 6.7 mm. Carapace 3.5 mm long, 2.7 wide, 1.6 behind lateral eyes. First femur 4.6 mm, patella and tibia 5.2, metatarsus 4.2, tarsus 1.4. Second patella and tibia 4.5 mm, third 2.1, fourth 3.1.

**Note.** This might be the male of *M. tapa*.

**Diagnosis.** The palpus of this species (Fig. 67) lacks the spine on the tegulum of
M. dubia (at 3 hr in Fig. 21) and has a smaller comb (at 1 hr in Fig. 66) than M. pimentel (Fig. 27). Most palpal sclerites differ slightly from those two similar species.

**Metazygia incerta** (O. P.-Cambridge)

**Figures 69–73; Map 2J**

*Epeira incerta* O. P.-Cambridge, 1889: 23, pl. 4, fig. 15, v. Female syntypes from Costa Rica, in BMNH, examined. Keyserling, 1892: 163, pl. 8, fig. 120, v.

*Epeira secunda* O. P.-Cambridge, 1889: 26, pl. 6, figs. 9, 10, v, d. Numerous syntypes from Guatemala in BMNH, examined. Keyserling, 1892: 164, pl. 8, fig. 121, v, d. First synonymized by F. P.-Cambridge, 1904.

*Aranea incerta*——F. P.-Cambridge, 1904: 512, pl. 49, figs. 7, 8, v, d. Roewer, 1942: 845.

**Synonymy.** There are male specimens in the vial with the female syntypes of *Epeira incerta*, which may have been added later. Keyserling reports *Epeira incerta* as coming from Guatemala, but both Keyserling and O. P.-Cambridge examined the same females. Paralectotypes of *Epeira maculata* (Levi, 1975) are this species; they are marked as coming from Baltimore, but this is an erroneous G. Marx locality.

**Description.** Female from San José, Costa Rica. Carapace orange-brown. Chelicerae, labium, endites orange. Sternum, coxae orange, legs brown. Dorsum of abdomen black and white (Fig. 72); venter dusky, some white pigment spots in center. Eyes subequal. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 6.5 mm. Carapace 2.7 mm long, 2.0 wide, 1.1 behind lateral eyes. First femur 2.9 mm, patella and tibia 3.6, metatarsus 2.6, tarsus 0.9. Second patella and tibia 2.9 mm, third 1.7, fourth 2.4.

Male from Monteverde, Costa Rica. Color as in female, but abdomen much darker. Posterior median eyes same diameter as anterior medians, laterals 0.9 diameter. Anterior median eyes their diameter apart, their diameter from laterals. Posterior median eyes 0.3 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Endite with small, sharp tooth, palpal femur with facing tubercle. First coxa with small hook. Second tibia thicker than first, without macrosetae. Total length 4.6 mm. Carapace 2.8 mm long, 2.2 wide, 1.2 behind lateral eyes. First femur 4.4 mm, patella and tibia 5.7, metatarsus 4.5, tarsus 1.2. Second patella and tibia 4.5 mm, third 2.2, fourth 4.0.

**Note.** Males and females were collected together.

**Variation.** Total length of females 4.5 to 9.0 mm, males 3.7 to 6.3. Illustrations were made from a female from San José, Costa Rica, and male from Puntarenas Prov., Costa Rica.

**Diagnosis.** The female differs from other *Metazygia* species by having the epigynum in ventral view an entire, rectangular plate, not showing openings (Fig. 69); the openings are anterior of the plate and not visible in ventral view. The male differs by having two teeth on the embolus lamella (L in Fig. 73), below the lamella’s sclerotized tip.

**Natural History.** Specimens were found in *Trypargilum nitidum* and *T. tenocitita* wasp nests at Cañas, Costa Rica. Most observations come from R. Buskirk (personal communication, 28 Feb. 1972). The observations were made in Monteverde, 1,350 m, Costa Rica. The orb is made in tree branches about 1 m above ground. Spiders are active in the hub at night from dusk to about 30 minutes to one hour after sunrise; during the day they are in folded-leaf retreats near or attached to the orb. The orbs are rebuilt every 2 to 4 days, depending on the damage to the web. In the Monteverde area, *M. incerta* is most abundant in moist habitats such as a river valley, and in places they are only a few decimeters above the water. Individual orbs
may be quite close to one another, nearly adjacent, but not continuous. Other collecting localities were rain forest, humid forest, cloud forest, a grapefruit orchard near a river, a porch at night, and mixed vegetation.

**Distribution.** Common from Belize to Panama (Map 2J).

**Specimens Examined.** BELIZE San Ignacio [17°10'N, 89°04'W] (MCZ). GUATEMALA Petén: E end Lago Petén Itzá (AMNH). Alta Vera Paz: Cobán (AMNH). HONDURAS Copan (AMNH); Lancetilla nr. **Metazygia pallidula** (Keyserling)

**Figures 74–80; Map 2E**

*Epeira pallidula* Keyserling, 1864: 124, pl. 4, figs. 14, 15. Ʌ. Female holotype from St. Fé de Bogota, New Granada [Bogotá, Colombia], in BMNH, examined. Keyserling, 1892: 158, pl. 8, fig. 116, Ʌ.

*Epeira simplicissima* Keyserling, 1883: 203, pl. 15, fig. 8. Ʌ. Female holotype from Tumbes [Tumbes, Depto. Tumbes], Peru, in PAN, examined. Keyserling, 1892: 169, pl. 8, fig. 125, Ʌ. NEW SYNONMY.

*Aranea pallidula*—F. P.-Cambridge, 1904: 514, pl. 49, fig. 13; Roewer, 1942: 449.

*Aranea simplicissima*—Roewer, 1942: 852.

*Araneus mollybyrnae*—Bonnet, 1955: 546.

*Araneus simplicissimus*—Bonnet, 1955: 600.

*Araneus pallides* Roewer, 1955: 1715. New name for *Epeira pallidula* Keyserling, thought to be preoccupied by *Araneus pallidula* Clerck, 1758 (=*Chubiona pallidula*).

**Synonymy.** The holotypes of *Epeira pallidula* and *Singa mollybyrnae* have the same large lateral openings of the epigynum. The holotype of *S. mollybyrnae* comes from Washington, D.C., and another specimen from Biscayne Bay, Florida. Each is an erroneous G. Marx locality.

**Description.** Female from Chiriquí Prov., Panama. Carapace orange, cephalic area dusky. Chelicerae, labium, endites, sternum orange. Coxae, legs orange, distally darker. Dorsum of abdomen whitish with anterior pair of black marks and indistinct dusky folium (Fig. 77); venter a white transverse patch posterior to the epigynum (Fig. 78). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.2 diameter apart, 2.8 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 5.6 mm. Carapace 2.3 mm long, 1.9 wide, 1.1 behind lateral eyes. First femur 2.7 mm, patella and tibia 3.1, metatarsus 2.3, tarsus 0.9. Second patella and tibia 2.7 mm, third 1.5, fourth 2.2.

Male from Chiriquí Prov., Panama. Color as in female, but legs with indistinct dark rings and no white on venter. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.6 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.5 mm. Carapace 2.5 mm long, 1.9 wide, 0.9 behind lateral. First femur 3.5 mm, patella and tibia 4.5, metatarsus 3.7, tarsus 1.2. Second patella and tibia 3.6 mm, third 1.8, fourth 2.5.

**Note.** Males and females are commonly collected together.

**Variation.** Total length of females 3.8
to 6.5 mm, males 2.5 to 4.2. Illustrations were made from specimens from Chiriquí Prov., Panama.

**Diagnosis.** The large pair of ear-like depressions on the ventral view of the epi-
gynum (Fig. 74) separates females from similar species. Males can be separated by the shape of the embolus with two rounded lobes "below" (Figs. 79, 80) and by the two pointed lobes of the embolus lamella (Fig. 79).

**Natural History.** Specimens were collected from a wet area near Acapulco, Mexico; from wet forest in Limón Prov., Costa Rica; on a bridge, banks of a river bed, and a rock wall in a garden in Chiriquí Prov., Panama; in a banana grove in Sullana, Peru; in light under the eaves of a house in northern Colombia; and in low shrubs and large herbs at night in Turrialba, Costa Rica. Many collections were made at night.

**Distribution.** From central Mexico to French Guiana and Ecuadorian and Pe-
ruvian coast (Map 2E).

**Specimens Examined.** MEXICO Veracruz: Coat-
zaacolas (AMNH); Tlacotalpan (AMNH). Guerrerio: 13 km W Acapulco (AMNH, MCZ); 2.4 km W Acapulco (AMNH); Acapulco (MCZ). Tabasco: Coma-
calco (AMNH). Chiapas: La Zacualpa (AMNH), EL SALVADOR San Salvador (AMNH), HONDURAS Comayagua (FSCA). **Metazygia enaba new species**

**Figures 81–86; Map 2E**

**Holotype.** Female holotype from Cerro de la Nebliña, base camp, 140 m, 050°N, 66°10’W, Trett. Federal Amazonas, Venezuela, 21–28 Feb. 1985, male para-
type, 9 Feb. 1985, both from low foliage (W. E. Steiner), in USNM. The specific name is an arbi-
trary combination of letters.

**Description.** Female holotype. Carapace light orange, eye region black. Che-
licerae distally much darker orange. La-
bium, endites dusky orange. Sternum, legs orange. Dorsum of abdomen with dense white pigment spots and two dark gray longitudinal bands; bands are most distinct posteriorly and become indistinct anteri-
orly (Fig. 54). Venter light dusky. Posterior median eyes 0.8 diameter of anterior me-
dians, laterals 0.7 diameter. Anterior med-
ian eyes 0.3 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.2 diameter of anterior median eye. Total length 3.7 mm. Carapace 1.8 mm long, 1.4 wide, 0.8 behind lateral eyes. First femur 1.6 mm, patella and tibia 1.8, metatarsus
1.1, tarsus 0.6. Second patella and tibia 1.6 mm, third 0.9, fourth 1.4.

Male paratype. Color as in female, but orange parts slightly dusky and dark bands of dorsum of abdomen more distinct. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.3 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 2.8 mm. Carapace 1.53 mm long, 1.17 wide, 0.57 behind lateral eyes. First femur 1.43 mm, patella and tibia 1.67, metatarsus 1.1, tarsus 0.59. Second patella and tibia 1.33 mm, third 0.88, fourth 1.14.

Note. Males and females were matched because both were collected at the same locality, in the same habitat, and have similar markings: longitudinal dark bands, darkest posteriorly (Fig. 84).

Diagnosis. The female epigynum differs from that of others by the ventrally projecting median plate (at 6 hr in Fig. 81, at center of Fig. 82) and the sclerotized edge of the lateral plates, as seen on each side in ventral view (Fig. 81). The male differs by the long, exposed embolus, which is not covered by the embolus lamella (Fig. 85).

**Metazygia redfordi** new species

**Figures 87–90; Map 2C**

*Holotype.* Female holotype from Parque Nacional das Emas, nr. Mineiros, Est. Goiás, Brazil, associated with a termite mound, Sept.–Oct. 1981 (K. H. Redford) in MZSP ex MCZ. The species is named after the collector.

Description. Female holotype. Carapace orange. Chelicerae, labium, endites orange. Sternum orange. Coxae orange, legs black. Dorsum of abdomen whitish with five pairs of black patches (Fig. 90); venter black except for book-lungs and area in-between, sides black. Posterior median eyes 0.6 diameter of anterior medians, anterior laterals 0.6 diameter, posterior laterals 0.5. Anterior median eyes 0.4 diameter apart, 1.5 diameters from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 7.5 mm. Carapace 3.7 mm long, 2.7 wide, 1.5 behind lateral eyes. First femur 2.8 mm, patella and tibia 3.5, metatarsus 2.2, tarsus 1.1. Second patella and tibia 3.1 mm, third 2.0, fourth 2.9.

Diagnosis. The contrasting markings on the abdomen (Fig. 90) would suggest that this species belongs in *Alpaida*; the epigynum (Figs. 87–89), however, is that of a *Metazygia*. Unlike that of other species, the scape is wide anteriorly (Fig. 87). The shape of the median plate in ventral and posterior view (Figs. 87, 88) is unlike that of other species.

**Metazygia isabelae** new species

**Figures 91–93; Map 2C**

*Holotype.* Male holotype from Santa Isabel do Morro, Ilha do Bananal, Est. Tocantins, Brazil, June 1961 (M. Alvarenga), in AMNH. The species is named after the local saint.

Description. Male holotype. Cephalothorax orange, the third and fourth coxae and legs lightest. Dorsum of abdomen light, with three faint, dusky, longitudinal bands (Fig. 93); venter light. Posterior median eyes 0.6 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.5 diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.2 diameter apart, 2.8 diameters from laterals. Height

*Scale lines.* 1.0 mm, genitalia 0.1 mm.
of clypeus equals 0.6 diameter of anterior median eye. Total length 4.8 mm. Carapace 2.8 mm long, 2.1 wide, 1.1 wide behind lateral eyes. First femur 3.1 mm, patella and tibia 3.9, metatarsus 3.4, tarsus 1.1. Second patella and tibia 3.2 mm, third 1.8, fourth 2.4.

**Diagnosis.** This male has an enlarged bubble-like subterminal apophysis (Figs. 91, 92) unlike that of any other species.

**Metazygia rogenhoferi** (Keyserling)

**Figures 94–99; Map 2C**

*Zilla rogenhoferi* Keyserling, 1878: 578, pl. 14, fig. 6, 8. Keyserling, 1892: 296, pl. 15, fig. 219. Female holotype from Brazil in NMW, examined.

**Description.** Female from Guaíba, Rio Grande do Sul. Carapace light orange. Chelicerae, labium, endites light orange. Sternum light orange. Legs light orange. Dorsum of abdomen white, with indistinct anterior dusky patches (Fig. 97). Venter with white pigment patches behind epigynum, on the sides and behind spinnerets (Fig. 98). Posterior median eyes 0.9 diameter of anterior medians, laterals 0.9 diameter. Anterior median eyes 1 diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.2 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. Total length 3.3 mm. Carapace 1.8 mm long, 1.4 wide, 0.7 behind lateral eyes. First femur 1.8 mm, patella and tibia 2.1, metatarsus 1.6, tarsus 0.7. Second patella and tibia 1.8 mm, third 1.1, fourth 1.5.

Male from Guaíba, Rio Grande do Sul. Color as in female, but with pairs of dusky brackets on dorsum of abdomen and abdomen with less white pigment. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.9 diameter. Anterior median eyes their diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.4 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Second tibia thinner than first, with few macrosetae. Total length 4.1 mm. Carapace 1.9 mm long, 1.6 wide, 0.7 behind lateral eyes. First femur 2.2 mm, patella and tibia 3.1, metatarsus 2.4, tarsus 0.9. Second patella and tibia 2.1 mm, third 1.2, fourth 1.6.

**Note.** Males and females were collected together.

**Variation.** Total length of females 3.4 to 5.6 mm, males 3.4 to 4.2. The lateral bracts framing the epigynum on each side (Fig. 94) are transparent and variable in shape. Illustrations were made from specimens from Guaíba, Rio Grande do Sul, Brazil.

**Diagnosis.** Females differ from other female *Metazygia* by having transparent bracts on each side of the epigynum, having a short scape (Fig. 94), and by the flask-shaped median plate as seen in posterior view (Fig. 95). Males are separated from others by the long sword-shaped embolus (Fig. 99).

**Natural History.** Specimens were collected with bromeliads in São Paulo state.

**Distribution.** From Bahia State to Rio Grande do Sul, Brazil (Map 2C).

**Specimens Examined.** BRAZIL: Bahia: Uruçuca, Fazenda Almada (MCN); Fazenda Jacarandá, Itamarajú (MCN). Rio de Janeiro: Rio de Janeiro, Pinheiro (MNRJ). São Paulo: Alto da Serra (MZSP); Barueri (MZR); Itanhaém, Baixo Rio Branco (MZSP); Campo Limpo, EFSD (AMNH); Juquiá, Fazenda Poço Grande (MZSP); Jurubatuba (MZSP); Osasco (MZSP); Ribeirão Pires (AMNH); Ilha de São Sebastião (MZSP); São Bernardo (MZSP). Rio Grande do Sul: Canela (MCN); Rio Grande, Estação Ecológica do Taim (MCN); Santa Vitória do Palmar, Estação, Ecológica do Taim (MCN); Guaíba, Granja Carola (MCN); Praia do Curumim (MCN); Torres, Triunfo (MCN); Viamão, Águas Belas (MCN); Viamão, Lagoa do Castamento (MCN).

**Metazygia barueri** new species

**Figures 100–103; Map 2F**

**Holotype.** Female holotype and male paratype from Barueri, Est. São Paulo, Brazil, 8 Sept. 1965 (K. Lenko), in MZSP no. 4026. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace light orange, cephalic region orange. Chelicerae brown. Labium, endites or-
Species, of the 0.5 eyes Carapace gray. Dark of sum Chelicerae, orange. Sternum orange. Tibia 2.1, tarsus 2.1, femur long, anterior median of 0.2. Carapace 1.5, diameter 2.8. Male to 2.4, 0.7. Carapace 1.2. Femur 1.6, patella 1.2, metatarsus 1.0, tarsus 0.7. Second patella and tibia 2.1 mm, third 1.3, fourth 1.9.

Diagnosis. Unlike the epigynum of other species, the area behind and on the side of the scaphe is wrinkled (Figs. 100–102).

Metazygia jamari new species
Figures 104–106; Map 2F
Holotype. Male holotype from Jamari, Rondônia, Brazil, 23 Jan. 1989 (Equipe Operação Jamari), in MCN no. 18550. The specific name is a noun in apposition after the type locality.

Description. Male holotype. Carapace orange. Chelicerae, labium, endites orange. Sternum orange. Legs orange. Dorsum of abdomen white with a pair of longitudinal dark bands (Fig. 106); venter gray. Carapace rebordered above first coxa. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.4 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Second tibia thinner than first. Total length 2.5 mm. Carapace 1.5 mm long, 1.1 wide, 0.5 behind lateral eyes. First femur 1.7 mm, patella and tibia 2.1, metatarsus 1.6, tarsus 0.7. Second patella and tibia 1.6 mm, third 0.8, forth 1.2.

Note. I was not successful matching this male to a female.

Variation. Total length of males 2.4 to 2.8. The Porto Velho male differed slightly in the shape of the embolus. It is not known if the horse shoe-shaped structure above the embolus (Figs. 104, 105) breaks off when mating. Illustrations were made from the holotype.

Diagnosis. Metazygia jamari differs from other species by the U-shaped tip of the embolus and by the straight terminal apophysis (at 12 hr to 2 hr in Fig. 104, left in Fig. 105).

Distribution. Amazon region (Map 2F).

Metazygia crewi (Banks)
Plate 1; Figures 107–113; Map 2I
Singa crewi Banks, 1903: 342, pl. 15, fig. 8, ?. Female holotype from Haiti, lost (not in AMNH, ANSP, CUC, MCZ, USNM). Roewer, 1942: 877.

Description. Female from Puerto Plata, Dominican Republic. Carapace dusky orange, black between eyes, margin of thoracic region darker. Chelicerae dusky orange. Labium, endites orange. Sternum light yellow-brown, black on each side, black fusing posteriorly to form a V shape. Legs light orange, distally with some dark rings. Dorsum of abdomen with dusky median band, a white cardiac mark, a white band on each side and black on sides (Fig. 110). Venter black with a square white patch posterior to genital groove, black surrounding spinnerets, sides light (Fig. 111). Carapace narrow in front without thoracic depression. Posterior median eyes 0.6 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 0.7 from laterals. Posterior median eyes 0.4 diameter apart, 2 diam-

M E T A Z Y G I A • L E V I  9 9
eters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 5.0 mm. Carapace 2.1 mm long, 1.6 wide, 0.7 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.5, metatarsus 1.9, tarsus 0.8. Second patella and tibia 1.9 mm, third 1.2, fourth 1.8.

Male specimen from Puerto Plata, Dominican Republic. Color as in female. Thoracic depression a longitudinal line. Posterior median eyes 0.7 diameter of anterior medians, anterior laterals 0.7, posterior 0.5. Anterior median eyes 1 diameter apart, slightly less from laterals. Posterior median eyes 0.4 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. First coxa with hook, fourth with a small macroseta. Total length 3.7 mm. Carapace 1.9 mm long, 1.5 wide, 0.6 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.9, metatarsus 2.2, tarsus 0.9. Second patella and tibia 2.0 mm, third 1.1, fourth 1.7.

**Note.** Males and females were collected together.

**Variation.** Total length of females 4.0 to 5.5 mm, males 3.3 to 3.7. Some females have three teeth on the anterior margin of the chelicerae, two on the posterior; others have four and three. The epigynum's transparent scape can be short (Fig. 107) or long and overhanging the anterior border of the epigynum; often it appears torn off with only a dark round scar. Illustrations were made from specimens collected in Puerto Plata, Dominican Republic; the web (Pl. 1) was photographed near Maricao, Puerto Rico.

**Diagnosis.** The female is separated from other species by having an epigynum that, when viewed posteriorly, has two long slits, separated by a narrow median plate (Fig. 108). The male is distinguished by having a palp with filamentous embolus and overhanging terminal apophysis (A) (Figs. 112, 113).

**Natural History.** Specimens were collected sweeping in forest on St. Johns, Virgin Islands, and in a coffee plantation at Jayuya, Puerto Rico. Many specimens came from an abandoned, dry, sunny road on a south-facing slope near Maricao, Puerto Rico, at 800 m elevation. The spiders had retreats in the heads of grass above a small transparent web (Pl. 1). These spiders could not be dislodged with a sweep net but had to be collected individually.

**Distribution.** Greater Antilles, Virgin Islands (Map 21).

**Abbreviations.** A, terminal apophysis; C, conductor; M, median apophysis; R, radix.

**Scale lines.** 1.0 mm, genitalia 0.1 mm.

**Metazygia varierorum** new species

*Figures 114–118; Map 21*

**Holotype.** Female holotype and one paratype from Variedades, 14°01’N, 90°30’W, Suchitepéquez, 120–170 m, Guatemala 27–31 Aug. 1947, and two female paratypes, 1–4 July 1947 (C. and P. Vaurie), in AMNH. The species is named after the collectors.

**Note.** The location of the type locality is published in Vaurie and Vaurie (1949).

**Description.** Female holotype. Carapace orange, cephalic region darker. Chelicerae dark orange-brown. Labium, endites, sternum orange. Coxae legs orange. Dorsum of abdomen with gray folium pattern on white (Fig. 117). Venter with transverse white patch behind epigynum and semicircular white line in front of spinnerets (Fig. 118). Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 6.0 mm. Carapace 3.5 mm long, 2.7 wide, 1.5 behind lateral eyes. First femur 3.4 mm, patella and tibia 4.1, metatarsus 3.2, tarsus 1.1. Second patella and tibia 3.6 mm, third 2.0, fourth 2.7.

**Diagnosis.** In ventral view the epigynum (Fig. 114) resembles that of *M. crewi* (Fig. 107), but the scape is a large knob rather than a flat plate (perhaps a piece has broken off). It differs in posterior view by having a wide median plate (Fig. 115).

**Metazygia carrizal** new species

*Figures 119, 120; Map 21*

**Holotype.** Male holotype from Mataquescuintla, El Carrizal, Depto. Jalapa, Guatemala, beating foliage at river, 25 Apr. 1982 (S. Fend), in CAS. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Carapace dusky orange to black. Chelicerae dusky orange. Labium black, endites orange. Sternum black. Coxae light orange, legs orange with dark rings. Dorsum of abdomen with median longitudinal light band and gray band to the side, whitish color to the sides of gray (Fig. 120). Venter dark with indistinct white pigment spots in center. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.3 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Second tibia thicker than first, with long macrosetae on both first and second tibiae. Total length 4.2 mm. Carapace 2.1 mm long, 1.5 wide, 0.8 behind lateral eyes. First femur 2.3 mm, patella and tibia 3.1, metatarsus 2.3, tarsus 0.9. Second patella and tibia 2.3 mm, third 1.2, fourth 1.8.

**Note.** This was collected near a *M. varierorum* female. However, it is considered to represent another species, as it has a different coloration: black sternum in male, light in female; white above cardiac area in male (Fig. 120), dark in female (Fig. 117).

**Diagnosis.** This species differs from all others by the terminal apophysis hanging “down” with its axis at an acute angle to the axis of the cymbium and by the shape of the sclerotized embolus lamella (at center of Fig. 119) and by the U-shaped embolus with a pointed cap (Fig. 119).

**Metazygia taman** new species

*Figures 121–124; Map 21*

**Holotype.** Female holotype from near Taman, ca. 16 km SW of Tamaulipan on Highway 55, 21°11’N, 98°53’W, ca. 300 m, San Luis Potosi State, Mexico, 11 June 1983 (W. Maddison, R. S. Anderson), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange, cephalic area dusky. Chelicerae, labium, endites orange-brown. Sternum dusky orange. Coxae, legs orange, distal articles darker. Dorsum of abdomen with paired dark gray marks on orange-
gray (Fig. 124); venter uniformly dark gray. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 1.4 diameters from laterals. Posterior median eyes 0.3 diameter apart. Posterior median eyes oval, the long diameter from median posterior, to lateral and anterior. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 7.7 mm. Carapace 3.9 mm long, 3.0 wide, 1.6 behind lateral eyes. First femur 3.3 mm, patella and tibia 3.9, metatarsus 2.5, tarsus 1.1. Second patella and tibia 3.4 mm, third 2.1, fourth 3.1.

**Diagnosis.** This species has a thinner scape (Figs. 121–123) than does *M. paquisha* (Figs. 125–127), but the scape is rounded (Fig. 123) and the posterior median plate is wider (Fig. 122) than that of *M. paquisha* (Fig. 126).

*Metazygia paquisha* new species

**Figures 125–128; Map 2H**

**Holotype.** Female holotype from Alto Río Comaina, Puesto de Vigilancia 22, "Falso Paquisha," Cordillera del Condor, border with Ecuador, 05°02'S, 78°51'W, Depto. Amazonas, Peru, night collecting, 23 Oct. 1987 (D. Silva D.), in MUSM. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange, darkest anterior. Chelicerae orange. Labium, endites, sternum dusky orange. Legs dusky orange, darkest distally. Abdomen gray without marks (Fig. 128). Carapace with a median line of setae. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 1.1 diameters from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 7.2 mm. Carapace 3.1 mm long, 2.3 wide, 1.3 behind lateral eyes. First femur 2.5 mm, patella and tibia 3.3, metatarsus 2.3, tarsus 0.9. Second patella and tibia 3.1 mm, third 2.1, fourth 2.5.

**Illustration.** Figures 125–128 were made from the holotype.

**Diagnosis.** The female differs from other species by the wide massive scape (Figs. 125–127) and from *M. taman* (Figs. 121–124) by the more pointed scape and narrower posterior plate (Figs. 126, 127).

**Distribution.** Amazon Region (Map 2H).

*Metazygia nobas* new species

**Figures 129–132; Map 2H**

**Holotype.** Female holotype from Baños, 1,600 m, Tungurahua Prov., Ecuador, July 1938, and paratype from Baños, 2,000 m, July–Aug. 1938 (W. C. Macintyre), in MCZ. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange. Chelicerae, labium, endites orange-brown. Sternum dark orange. Legs orange. Dorsum of abdomen light with a faint folium and spots (Fig. 132); venter gray without marks. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1.7 diameters from laterals. Posterior median eyes 0.2 diameter apart, 2.5 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 8.6 mm. Carapace 4.0 mm long, 2.9 wide, 1.9 behind lateral eyes. First femur 3.0 mm, patella and tibia 3.6, metatarsus 2.3, tarsus 1.1. Second patella and tibia 3.2 mm, third 2.2, fourth 2.9.

**Diagnosis.** The epigynum (Figs. 129–131) differs from that of the Mexican *M. taman* (Figs. 121–123) and the Colombian *M. cheneve* (Figs. 177–179) by having the median anterior edge of the base sclerotized (at 12 hr in Fig. 129) and the posterior median plate heart-shaped (Fig. 130). *Metazygia nobas* differs from *M. paquisha* (Fig. 126) in the wider posterior median plate (Fig. 130). The posterior margin of the epigynum base in ventral view has a notch on each side (at 7 hr and 5 hr in Fig. 129) resembling that of *M. voluptifica* (Fig. 280).
**Metazygia goeldii new species**  
*Figures 133–137; Map 2K*

*Holotype.* Female holotype from Goeldi Museum, Belém, Est. Pará, Brazil, 10 Feb. 1959 (A. M. Nadler), in AMNH. The species is named after the Brazilian naturalist E. Goeldi.

**Description.** Female holotype. Carapace orange. Chelicerae, labium, endites dark orange. Sternum orange. Coxae light-est orange, legs dusky orange. Dorsum of abdomen light with gray folium (Fig. 137); venter light dusky. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 1.2 diameters from laterals. Posterior median eyes 0.2 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 6.0 mm. Carapace 2.8 mm long, 2.3 wide, 1.2 behind lateral eyes. First femur 2.4 mm, patella and tibia 2.9, metatarsus 2.0, tarsus 0.9. Second patella and tibia 2.5 mm, third 1.7, fourth 2.3.

**Variation.** Total length of females 4.7 to 6.0 mm. The shape of the scape in the two specimens differs (Figs. 133, 136). Illustrations (Figs. 133–135, 137) were made from the female holotype.

**Diagnosis.** The abdomen is oval, widest in anterior half (Fig. 137). *Metazygia goeldii* differs from others by the knob-shaped scape (Figs. 133–135), which appears curved in lateral view (Fig. 135).

**Metazygia arnoi new species**  
*Figures 138–141; Map 2H*

*Holotype.* Female holotype from Lago do José, Manaús, Amazonas State, Brazil, 9 Aug. 1987 (J. Adis et al.), in MCN no. 20058. The species is named after the collector.

**Description.** The female holotype has lost all white pigment including the silver tapetum; it apparently was collected in a preservative other than alcohol (Levi, 1989). The specimen is all orange, except for a black band around anterior of abdomen which is in the middle (Fig. 141). The eye region is black. Posterior median eyes same diameter as anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Abdomen slightly flattened anteriorly (Fig. 141). Total length 3.7 mm. Carapace 1.8 mm long, 1.3 wide, 0.7 behind lateral eyes. First femur 1.9 mm, patella and tibia 2.5, metatarsus 1.8, tarsus 0.6. Second patella and tibia 2.1 mm, third 1.2, fourth 1.8.

**Diagnosis.** Unlike other species, *Metazygia arnoi* has framed bulges on each side of the scape of the epigynum (Figs. 138, 139).

**Metazygia paquisha.**  
*Figures 142, 143; Map 2H*

**Description.** Male holotype. Carapace orange. Chelicerae orange. Labium, endites, orange. Sternum orange, slightly dusky. Coxae; legs orange. Dorsum of abdomen light gray with faint dusky marks, pairs of spots and outline of folium (Fig. 143); venter light gray. Carapace with median longitudinal line. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 0.4 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 5.1 mm. Carapace 2.6 mm long, 2.1 wide, behind lateral eyes 0.8 wide. First femur 2.4 mm, patella and tibia 2.7, metatarsus 2.0, tarsus 0.8. Second patella and tibia 2.3 mm, third 1.4, fourth 1.9.

**Note.** This might be the male of *M. paquisha.*

**Diagnosis.** The palpus (Fig. 142) lacks a terminal apophysis and differs from all others by the loop of the thread-shaped embolus (at 12 hr in Fig. 142).

Figures 142, 143. *M. arnoi* n. sp., male. 142, left male palpus. 143, dorsal.

Figures 144–149. *M. curari* n. sp. 144–147, female. 144–146, epigynum. 144, ventral. 145, posterior. 146, lateral. 147, dorsal. 148, 149, male palpus. 148, mesal. 149, ventral.

*Scale lines.* 1.0 mm, genitalia 0.1 mm.
**Metazygia curari** new species
*Figures 144–149; Map 2H*

**Holotype.** Female holotype from Ilha de Curari, Manaús, Est. Amazonas, Brazil, 3 Aug. 1987 (J. Adis et al.), in MCN no. 20055. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace yellowish white, little black between eyes. Chelicerae, labium, endites yellowish white. Sternum, legs yellowish white. Dorsum of abdomen with two longitudinal white lines on dusky white (Fig. 147); venter yellowish white. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 1.2 diameters apart, 0.4 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.3 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 2.7 mm. Carapace 1.25 mm long, 0.97 wide, 0.49 behind lateral eyes. First femur 1.38 mm, patella and tibia 1.61, metatarsus 1.11, tarsus 0.49. Second patella and tibia 1.32 mm, third 0.82, fourth 1.28.

**Male.** Color as in female but distal articles of legs dusky. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.4 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.1 diameter apart, 1.2 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Endite with pointed tooth. Second tibia thicker than first, proximally swollen with macrosetae. Total length 2.5 mm. Carapace 1.32 mm long, 1.05 wide, 0.66 behind lateral eyes. First femur 1.30 mm, patella and tibia 1.61, metatarsus 1.13, tarsus 0.59. Second patella and tibia 1.32 mm, third 0.84, fourth 1.09.

**Note.** Males and females were matched because both have similar median white lines on the abdomen and little black pigment between eyes. Their collecting localities are within 10 km of each other. A recently collected female had a green abdomen.

**Diagnosis.** The pair of longitudinal white lines on the abdomen (Fig. 147) is a distinctive character. In ventral view of the epigynum, the median plate overlaps the lateral plates along their posterior margins (at 8 hr, and at 4 hr in Fig. 144). The palpus lacks a terminal apophysis and the embolus has a distinctive shape (Fig. 148).

**Specimens Examined.** BRAZIL, Amazonas: Manaús, Canal Januari, mixed water forest, 16, 17 June 1987, 15 (H. Höfer, INPA); Ilha de Marchantaria, Rio Solimões, 3°15'S, 60°59'W, 2 Sept. 1992, 15 (J. Adis et al., INPA).

**Metazygia bolivia** new species
*Figures 150–153; Map 2F*

**Holotype.** Female holotype from Est. Biológico Beni, Zone 3, ca. 14°47'S, 66°15'W, ca. 225 m, Depto. Beni, Bolivia, 8–14 Nov. 1989 (J. Coddington, S. Larcher, C. Griswold, D. Silva D., E. Pañaranda), in IELP. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange, sides of thoracic region lightest. Chelicerae orange-brown. Labium, endites dark orange. Sternum orange. Coxae light orange, legs dusky orange. Dorsum of abdomen with white pigment spots and pairs of gray brackets (Fig. 153); venter light gray. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.4 diameter apart. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 6.7 mm. Carapace 3.0 mm long, 2.0 wide, 1.5 behind lateral eyes. First femur 2.2 mm, patella and tibia 2.5, metatarsus 1.8, tarsus 0.8. Second patella and tibia 2.3 mm, third 1.5, fourth 2.0.

**Diagnosis.** The elongate abdomen (Fig. 153) suggests that this species may belong to another genus, as yet unnamed, whose species have a cylindrical abdomen. However, the epigynum is of the characteristic shape found in *Metazygia*, although the flat scape is larger than in other species (Figs. 150–152).

**Metazygia yucumo** new species
*Figures 154–163; Map 2K*

**Holotype.** Female holotype, female and male paratypes from 26.9 km SW Yucumo, 500 m, ca. 15°23'S, 66°59'W, Depto. Beni, Bolivia, 15–19 Nov. 1989 (J.
Coddington, C. Grisswold, D. Silva D., S. Larcher, E. Pañaranda), in USNM. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace light orange-yellow. Chelicerae, labium, endites orange-yellow. Sternum, coxae orange-yellow. Legs orange-yellow, except distal half of first femora with brown ring, underside black, and first two tibiae and distal articles brown, underside darker. Dorsum of abdomen white without pattern (Figs. 157, 161); venter light gray. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes their diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.2 mm. Carapace 2.0 mm long, 1.4 wide, 0.8 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.7, metatarsus 1.8, tarsus 0.7. Second patella and tibia 2.2 mm, third 1.1, fourth 1.8.

Male. Color as in female. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes their diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. First femur with many macrosetae (Fig. 163). Total length 4.2 mm. Carapace 1.9 mm long, 1.3 wide, 0.6 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.9, metatarsus 2.3, tarsus 0.9. Second patella and tibia 2.3 mm, third 1.1, fourth 1.7.

**Note.** Males and females were collected together.

**Variation.** Total length of females 3.7 to 4.5 mm. The openings of the epigynum may be indistinct and hard to see (Fig. 154); some have a lip laterally (Fig. 158). Illustrations were made from the female holotype (Figs. 158–161) and a female from Mitú, Colombia (Figs. 154–157), and the male paratype.

**Diagnosis.** The female is separated from others by the epigynum, which has an indistinct pair of anterior median openings on each side of a thin scape (at 11 hr and at 1 hr in Figs. 154, 158). The male has a brush of ventral setae on the underside of the femur (Fig. 163), and the tip of the embolus is hook-shaped (Fig. 162).

**Distribution.** Upper Amazon region (Map 2K).

**Metazygia ipanga** new species

**Figures 164–167; Map 2K**

**Holotype.** Female holotype from Museum Park, Ipiranga, São Paulo, Est. São Paulo, Brazil, 6 Dec. 1960 (J. Luiz), in MZSP no. 7642. The specific name is an arbitrary combination of letters.

**Note.** Ipiranga is the district of the city of São Paulo in which the MZSP is located.

**Description.** Female holotype. Cephalothorax very light orange, only eyes with black pigment. Dorsum of abdomen whitish with faint black band around anterior (Fig. 167). Venter whitish without pigment. Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.7 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 4.5 mm. Carapace 1.9 mm long, 1.4 wide, 0.8 behind lateral eyes. First femur 2.2 mm, patella and tibia 2.5, metatarsus 2.0, tarsus 0.6. Second patella and tibia 2.0 mm, third 1.2, fourth 1.8.

**Variation.** The holotype lacks white pigment; it appears washed out by the preserving fluid (Levi, 1989). The specimen from the Chaco Prov., Argentina, had both sides of the abdomen white and white pigment spots anterior to the black band. The Bolivian specimen had black pigment between the eyes and a square white pigment area on the venter of the abdomen. The holotype was illustrated.

**Diagnosis.** The abdomen is spherical (Fig. 167). This species differs from *M.*
urario\textit{c}o}\textit{ra} by the shape of the posterior median plate of the epigynum (Fig. 165).

\textit{Distribution}. São Paulo State, northern Argentina to Bolivia (Map 2K).

\textit{Metazygia urario\textit{c}o}\textit{ra} new species

\textit{Figures} 168–171; \textit{Map} 2K

\textit{Holotype}. Female holotype from Ilha de Maracá, Rio Uraicoera, Est. Roraima, Brazil, 20 Mar. 1987 (A. A. Lise), in MCN no. 20064. The specific name is a noun in apposition after the type locality.

\textit{Description}. Female holotype. Carapace orange, eye region black. Chelicerae dark orange. Labium, endites dark orange. Sternum orange. Legs orange. First femur with a distal black spot on underside, distal end of first tibia dark. Dorsum of abdomen white with an anterior pair of black spots (Fig. 171). Venter with a white longitudinal band, starting at the side of book-lung covers. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.3 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. All patellae with a posterior, blunt tubercle. Total length 3.1 mm. Carapace 1.4 mm long, 1.1 wide, 0.5 behind lateral eyes. First femur 1.4 mm, patella and tibia 1.6, metatarsus 1.2, tarsus 0.5. Second patella and tibia 1.3 mm, third 0.8, fourth 1.1.

\textit{Variation}. Total length of females 3.1 to 4.4 mm. The specimen from Surinam had the epigynum slightly shorter in posterior view and the abdomen more elongate. Illustrations were made from the holotype.

\textit{Diagnosis}. The epigynum of this species, unlike that of others, has a sclerotized notch anteriorly on each side (at 10 hr and at 2 hr in Fig. 168) and a long narrow posterior median plate (Fig. 169).

\textit{Natural History}. The specimen collected in Guyana came from forest savanna.

\textit{Distribution}. Guianas to northern Brazil (Map 2K).

\textit{Metazygia serian} new species

\textit{Figures} 172–176; \textit{Map} 21

\textit{Holotype}. Female holotype from La Selva, 4 km SE of Puerto Viejo, Heredia Prov., Costa Rica, 7 Aug. 1980, probably from wasp nest (B. Coville), in MCZ. The specific name is an arbitrary combination of letters.

\textit{Description}. Female holotype. Carapace orange, cephalic region brown, eye region black. Chelicerae dark brown to black. Labium, endites brown. Sternum orange. Coxae, legs orange. Dorsum of abdomen with dense white pigment spots and transverse black band around anterior (Fig. 175). Venter white with a large white square between epigynum and spinnerets (Fig. 176). Posterior median eyes 0.9 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.2 diameters from laterals. Height of

---

Figures 185–188. *M. atalaya* n. sp., female. 185–187, epigynum. 185, ventral. 186, posterior. 187, lateral. 188, dorsal.

Scale lines. 1.0 mm, genitalia 0.1 mm.
clypeus equals 0.7 diameter of anterior median eye. Total length 5.0 mm. Carapace 1.8 mm long, 1.5 wide, 0.9 behind lateral eyes. First femur 2.2 mm, patella and tibia 2.6, metatarsus 1.8, tarsus 0.6. Second patella and tibia 2.2 mm, third 1.2, fourth 1.9.

**Variation.** Total length of females 4.8 to 5.0 mm. Living specimens are green (Eberhard, in letter). Illustrations were made from the holotype.

**Diagnosis.** The abdomen is subspherical, widest in anterior half (Fig. 175). This species resembles the tetragnathid genus *Chrysometa* in general appearance and epigynum (but not the coloration). In ventral view, the epigynum has openings close to the posterior margin (Fig. 172), unlike any other *Metazygia* species.

**Metazygia chenevo new species**

*Figures 177–180; Map 3A*

**Holotype.** Female holotype from Finca Chenevo, 175 m elev., 20 km S El Porvenir, 20 km N Río Muco, Depto. Meta, Colombia, 1978 (W. Eberhard, no. 1386), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange, cephalic region orange-brown. Chelicerae brown. Labium, endites orange. Sternum orange. Coxae lighter orange; legs dusky orange. Dorsum of abdomen with three longitudinal dusky bands on white (Fig. 180), sides and venter gray. Posterior median eyes 0.6 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.8 diameter apart, 1.5 diameters from laterals. Posterior median eyes 0.2 diameter apart, 3 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 6.0 mm. Carapace 2.9 mm long, 2.2 wide, 1.3 behind lateral eyes. First femur 2.7 mm, patella and tibia 3.1, metatarsus 2.1, tarsus 0.9. Second patella and tibia 2.7 mm, third 1.7, fourth 2.2.

**Diagnosis.** Unlike the Ecuadorian *M. nobas* (Fig. 130), the posterior median plate of the epigynum has a lateral constriction in posterior view (Fig. 178).

**Distribution.** Amazon drainage, Colombia to Guyana (Map 3A).

**Specimen Examined.** GUYANA Rupununi Savanna, swamp, Sept.–Oct. 1959, 1♀ (S. Djojosudharmo, F. Mees, CD).

**Metazygia lazepa new species**

*Figures 181–184; Map 3A*

**Holotype.** Female holotype from Hacienda Mozambique, 15 km SW Puerto Lopez, 200 m, Depto. Meta, Colombia, Aug. 1978 (W. Eberhard, no. 1812), in MCZ. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange, cephalic region orange-brown. Chelicerae brown. Labium, endites orange brown. Sternum, coxae orange; legs dark orange. Dorsum of abdomen light gray with pairs of gray brackets (Fig. 184); venter gray without markings. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 1 diameter from laterals. Posterior median eyes 0.2 diameter apart, 2.5 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 8.8 mm. Carapace 3.8 mm long, 3.1 wide, 2.0 behind lateral eyes. First femur 3.4 mm, patella and tibia 3.9, metatarsus 2.9, tarsus 1.2. Second patella and tibia 3.4 mm, third 2.1, fourth 3.1.

**Diagnosis.** Unlike other *Metazygia*, the posterior plate of the epigynum is wide and completely covers the lateral plates (Figs. 181, 182). The holotype was illustrated.

**Distribution.** Colombia, Venezuela (Map 3A).

**Specimen Examined.** VENEZUELA Carabobo; San Esteban, 26 Jan. 1940, 1♀ (P. Andruze, AMNH).

**Metazygia atalaya new species**

*Figures 185–188; Map 3A*

**Holotype.** Female holotype from Atalaya, Río Carbón, night collecting, Depto. Cuzco, Peru, 23 Sept.
1987 (D. Silva D.), in MUSM. The specific name is a noun in apposition after the type locality.

Description. Female holotype. Carapace orange. Chelicerae, labium, endites dark orange. Sternum orange. Legs dusky orange. Abdomen gray without any marks (Fig. 188). Posterior median eyes 0.7 diameter of anterior medians, anterior laterals 0.7 diameter, posterior 0.6. Anterior median eyes 0.7 diameter apart, 1.1 diameters from laterals. Posterior median eyes 0.2 diameter apart. Posterior median eyes slightly oval. Height of clypeus equals 0.3 diameter of anterior median eye. The abdomen is slightly pointed anteriorly (Fig. 188). Total length 7.5 mm. Carapace 3.2 mm long, 2.4 wide, 1.4 behind lateral eyes. First femur 2.9 mm, patella and tibia 3.4, metatarsus 2.5, tarsus 1.2. Second patella and tibia 3.1 mm, third 1.9, fourth 2.7.

Diagnosis. The abdomen is slightly pointed anteriorly (Fig. 188). The epigynum of this species differs from that of others by the unusual shape of the scape (Figs. 185–187).

Metazygia corima new species

Figures 189–192; Map 3B

Holotype. Female holotype from Carimagua, 100 m, Depto. Meta, Colombia, grass, brush along fence, Oct. 1973 (W. Eberhard), in MCZ. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange, cephalic region brown. Chelicerae brown. Labium, endites orange. Sternum dark orange. Coxae, legs orange. Dorsum of abdomen with a median longitudinal light band that is bordered by darker ones (Fig. 192). Sides, venter gray. Posterior median eyes 0.7 diameter of anterior medians, anterior laterals 0.7 diameter, posterior 0.6. Anterior median eyes 0.6 diameter apart, 1 diameter from laterals. Posterior median eyes 0.4 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 5.5 mm. Carapace 2.7 mm long, 1.7 wide, 1.1 wide behind lateral eyes. First femur 2.3 mm, patella and tibia 2.7, metatarsus 1.9, tarsus 0.8. Second patella and tibia 2.4 mm, third 1.5, fourth 2.1.

Diagnosis. The epigynum and scape resembles that of Araneus tiganus (Chamberlin) (Levi, 1991a, figs. 9–11); the scape is oval in ventral view (Fig. 189).

Metazygia uratron new species

Figures 193–196; Map 3A

Holotype. Female holotype from Fazenda Santo Antonio, Uruguca, Bahia, Brazil, 24 Oct. 1978 (J. S. Santos), in MCN no. 1097. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange. Chelicerae dark orange. Labium, endites orange. Sternum light orange, with irregular dusky spots. Coxae light orange, legs orange. Dorsum of abdomen dusky with darker gray folium outline (Fig. 196). Venter gray without marks. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 1.5 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 7.0 mm. Carapace 3.4 mm long, 2.5 wide, 1.5 behind lateral eyes. First femur 3.1 mm, patella and tibia 3.3, metatarsus 2.3, tarsus 1.1. Second patella and tibia 2.7 mm, third 1.9, fourth 2.7.

Diagnosis. This species differs from other Metazygia by the shape of the large scape (Figs. 193–195).

Metazygia saturnino new species

Figures 197–202; Map 3A

Holotype. Male holotype and immature male from Barragem Saturnino de Brito, Santa Maria, Rio Grande do Sul, Brazil, 7 July 1982 (M. Rosenau), in MCN no. 10596. The specific name is a noun in apposition after the type locality.

and distal articles darkest. Dorsum of abdomen with gray pattern on light gray (Fig. 200); venter light gray. Posterior median eyes 0.6 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 5.3 mm. Carapace 2.5 mm long, 2.1 wide, 1.2 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.5, metatarsus 1.7, tarsus 0.8. Second patella and tibia 2.3 mm, third 1.3, fourth 1.8.

Male holotype. Color as in female but sternum and coxae are both orange. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.2 diameter apart, 2 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. First coxa with minute hook. Second tibia as thick as first. Total length 4.5 mm. Carapace 2.3 mm long, 1.9 wide, 0.8 wide behind lateral eyes. First femur 2.7 mm, patella and tibia 3.3, metatarsus 2.5, tarsus 1.1. Second patella and tibia 2.8 mm, third 1.4, fourth 1.9.

Note. Males and females were matched because of similar size and dark cephalic region of carapace.

Variation. The epigynum of the female is probably broken off (Figs. 197–199).

Diagnosis. The base of the epigynum appears broken. The epigynum has a long, wide posterior median plate (Fig. 198). The male differs from that of *M. crabroniphila* (Fig. 207) by the shape of the conductor and the much larger radix (Fig. 201).

Metazygia crabroniphila Strand
Figures 203–207; Map 3B

Aranea (Metazygia) crabroniphila Strand, 1915: 117. Female and male syntypes from Joinville, Est. Santa Catarina, Brazil, in SMF. examined.

Description. Female from Jurubatuba, Est. São Paulo. Carapace light orange, cephalic region orange. Chelicerae brown. Labium, endites dark orange. Sternum orange. Coxae light orange; legs orange, distal articles darker. Dorsum of abdomen with a pair of anterior dusky patches and pairs of diagonal marks (Fig. 206); venter light, without marks. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1 diameter from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 5.5 mm. Carapace 2.4 mm long, 1.8 wide, 1.1 wide behind lateral eyes. First femur 2.1 mm, patella and tibia 2.6, metatarsus 1.6, tarsus 0.5. Second patella and tibia 2.3 mm, third 1.3, fourth 1.8.

Male from Pinhal, Santa Catarina, Brazil. Color as in female. Posterior median eyes 0.8 diameter of anterior medians, anterior laterals 0.8 diameter, posterior laterals 0.6. Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. First coxa without hook. Total length 4.0 mm. Carapace 2.5 mm long, 1.8 wide, 0.9 wide behind lateral eyes. First femur 2.4 mm, patella and tibia 3.1, metatarsus 2.2, tarsus 0.9. Second patella and tibia 2.7 mm, third 1.3, fourth 1.8.

Variation. Total length of females 4.5 to 8.0 mm, males 4.0 to 4.3. It is uncertain whether the scape of the epigynum is torn off in all examined or is a minute bulge (Fig. 203). Illustrations were made from a female and male from Pinhal. The dorsal view is of a female from Jurubatuba.

Diagnosis. The female can be separated from others by the two oval sclerotized plates of the epigynum (Fig. 203). The male can be distinguished from *M. saturnino* by having a straight conductor (at 3 hr in Fig. 207) and a longer median apophysis (at 4 hr and at 5 hr in Fig. 207).

Natural History. Most examined spec-
Metazygia • Levi 113

*Scale lines.* 1.0 mm, genitalia 0.1 mm.

imens are in poor condition and may all have come from wasp nests.

*Metazygia matanzas* new species Figures 208–212; Map 2J

**Holotype.** Female holotype from Pan de Palenque, Matanzas, Cuba, 11 Aug. 1955 (A. F. Archer), in AMNH. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace dusky orange, darkest in eye region.
Chelicerae, labium, endites dusky orange. Sternum orange with sides black. Coxae orange, legs dusky orange. Dorsum of abdomen with black bands on sides, bordered by white bands, and an indistinct dusky folium containing anterior black marks (Fig. 211). Venter with white patch on black (Fig. 212). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.7 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 3.9 mm. Carapace 1.6 mm long, 1.2 wide, 0.7 wide behind lateral eyes. First femur 1.4 mm, patella and tibia 1.8, metatarsus 1.1, tarsus 0.7. Second patella and tibia 1.5 mm, third 0.9, fourth 1.2.

**Diagnosis.** This species may belong to *Araneus* because it has an annulate, flattened round scape (Fig. 208). It is placed here because of the shape of the abdomen and the position of the posterior median eyes (Fig. 211).

**Metazygia corumba** new species

**Figures 213–215; Map 3B**

**Holotype.** Male holotype and male paratype (with one female of *M. voluptifera*) from Corumbá, Mato Grosso do Sul, Brazil, 28–29 May 1960 (B. Malkin), in AMNH. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Cephalothorax orange. Dorsum of abdomen white with sides dusky. Venter with white patch behind genital groove (Fig. 215). Posterior median eyes 0.8 diameter of anterior medians, anterior laterals 0.8 diameter, posterior laterals 0.7. Anterior median eyes 0.6 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.7 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Endite without tooth. First coxa with small hook. Total length 5.2 mm. Carapace 2.5 mm long, 2.0 wide, 1.0 wide behind lateral eyes. First femur 2.6 mm, patella and tibia 3.2, metatarsus 2.4, tarsus 0.9. Second patella and tibia 2.7 mm, third 1.5, fourth 2.0.

**Note.** The two males from Corumbá were collected with a female of *M. munda.*

**Variation.** Total length of males 3.7 to 5.2 mm. Illustrations were made from the holotype.

**Diagnosis.** This species differs from *M. crabroniphila* by having the two edges of the embolus straight and parallel (Fig. 213).

**Specimen Examined.** BOLIVIA Santa Cruz: Matatal, 14 Dec. 1984, 1♀ (L. Peña, AMNH).

**Metazygia sendero** new species

**Figures 216–221; Map 3B**

**Holotype.** Female holotype from Sendero Campamento, Laguna Grande, PUCE Field Station, Reserve Faunistica Cuyabeno, 00°00′N, 76°10′11″W, 31 July to 5 Aug. 1988, Suscumbios Prov., Ecuador, 31 July to 5 Aug. 1988 (W. Maddison), in MECN. The specific name is a noun in apposition after the type locality; sendero is the Spanish word for path.

**Description.** Female holotype. Carapace orange and black. Chelicerae brownish black. Labium, endites brown. Sternum brown. Coxae dusky orange, legs dark orange-brown. Dorsum of abdomen with a series of pairs of black brackets (Fig. 219). Venter with a black square (Fig. 220). Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 2.2 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 11.0 mm. Carapace 4.6 mm long, 3.2 wide, 2.5 behind lateral eyes. First femur 3.5 mm, patella and tibia 4.5, metatarsus 3.1, tarsus 1.4. Second patella and tibia 3.9 mm, third 2.2, fourth 3.4.

Male. Coloration as in female, but venter of abdomen with scattered white pigment spots. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.4 diameter apart, 1.6 diameters from laterals. Posterior median eyes 0.4 diameter apart, 3.5 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior

Figures 222–225. *M. uma* n. sp. 222–224, female. 222, 223, epigynum. 222, ventral. 223, posterior. 224, right, dorsal; left, abdomen, ventral. 225, male palpus.

Scale lines. 1.0 mm, genitalia 0.1 mm.
median eye. Total length 6.5 mm. Carapace 3.2 mm long, 2.3 wide, 1.5 behind lateral eyes. First femur 2.5 mm, patella and tibia 3.1, metatarsus 2.3, tarsus 1.2. Second patella and tibia 2.7 mm, third 1.5, fourth 2.1.

Note. Males and females were matched because of similar coloration, a similar wide cephalic region and swelling behind the eyes, and similarly shaped abdomen. The only other species with these characters is *M. laticeps*. Male and female come from the opposite slopes of the Andes.

**Variation.** Total length of females 8.0 to 11.0 mm. Illustrations were made from the female holotype and a male from Tinalandia, Ecuador.

**Diagnosis.** The abdomen is elongate, oval, slightly overhanging spinnerets (Fig. 220). This species differs from *M. laticeps* by having the epigynum with a narrower triangle in ventral view (Fig. 216); in posterior view, the median plate is as wide as long (Fig. 217) while that of *M. laticeps* is narrow (Fig. 227). The median apophysis of the palpus (at 4 hr in Fig. 221) has two tips.

**Distribution.** Ecuador, Peru (Map 3B).

**Metazygia uma new species**

**Figures 222–225; Map 3B**

**Holotype.** Female holotype from Puesto de Vigilancia Pakitza, Zona Reservada de Manu, Depto. Madre de Dios, 11°58’S, 71°18’W, Peru, inundated forest, 30 Sept. 1987 (D. Silva D., J. Coddington), in MUSM. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange. Chelicerae, labium, endites orange. Sternum orange. Coxae orange; legs orange but distal tips of tibiae, metatarsi and tarsi black. Dorsum of abdomen with longitudinal gray lines (Fig. 224); venter with a black rectangle (Fig. 225).

Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 3 diameters from laterals. Posterior median eyes 0.4 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 8.2 mm. Carapace 3.8 mm long, 2.5 wide, 2.3 behind lateral eyes. First femur 2.6 mm, patella and tibia 3.4, metatarsus 2.3, tarsus 1.1. Second patella and tibia 2.9 mm, third 1.7, fourth 2.7.

Male. Coloration as in female, but venter of abdomen all black. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.5. Anterior median eyes 0.8 diameter apart. Posterior median eyes 0.3 diameter apart. Coxal hook very small. Second tibia thicker than first with two long macrosetae in a line. Height of clypeus equals 1 diameter of anterior median eye. Total length 3.9 mm. Carapace 2.0 mm long, 1.4 diameters wide, 0.9 wide behind lateral eyes. First femur 1.4 mm, patella and tibia 1.8, metatarsus 1.2, tarsus 0.7. Second patella and tibia 1.5 mm, third 0.8, fourth 1.1.

Note. Male was matched with the female because of similar coloration and the relatively wide cephalic region of the carapace.

**Diagnosis.** This species is distinct in that the eye region of the carapace is almost as wide as the thoracic region (Fig. 224). The male differs from *M. laticeps* by the curved embolus lamella with a short curved embolus “above” it (Fig. 225). This strange-looking species is apparently a *Metazygia* and closest to *M. laticeps*, which has also the carapace relatively wide anteriorly (Fig. 228).

**Natural History.** The male was collected in forest interior.

**Distribution.** Amazon region, Peru to Brazil (Map 3B).

**Metazygia laticeps** (O. P.-Cambridge), new combination
Figures 226–230; Map 3F

_Epeira laticeps_ O. P.-Cambridge, 1889: 18, pl. 4, fig. 16, ? Female holotype from Bugaba, Panama, in BMNH no. 1890.7.15020, examined. Keyserling, 1892: 175, pl. 8, fig. 129, 9.
_Araneus laticeps:_—F. P.-Cambridge, 1904: 516, pl. 49, fig. 21, ?. Roewer, 1942: 845.
_Araneus laticeps:_—Bonnet, 1955: 527.

**Note.** The type specimen belonged to Keyserling. The vial containing the type also contains Keyserling’s original, toothed, blue-bordered label, which is still faintly legible when dried. The first line reads Guatemala and not Bugaba.

**Description.** Female from Pipeline Road, Panama. Carapace dark orange with median double line, black on each side of thoracic region. Chelicerae, labium, endites orange. Sternum dusky orange-brown. Coxae light orange, legs dusky orange-brown. Dorsum of abdomen with pairs of brackets (Fig. 228); venter with median dark gray patch (Fig. 229). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.8 diameter apart, 2 diameters from laterals. Posterior median eyes 0.6 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 10.0 mm. Carapace 3.7 mm long, 3.1 wide, 2.2 behind lateral eyes. First femur 3.4 mm, patella and tibia 4.4, metatarsus 2.7, tarsus 1.3. Second patella and tibia 3.7 mm, third 2.2, fourth 3.2.

Male from Barro Colorado Island, Panama. Color as in female. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 2.5 diameters from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.4 diameter of anterior median eye. Abdomen as in female, but smaller. Total length 6.3 mm. Carapace 3.4 mm long, 2.5 wide, 1.7 behind lateral eyes. First femur 2.9 mm, patella and tibia 3.8, metatarsus 2.7, tarsus 1.2. Second patella and tibia 3.1 mm, third 1.7, fourth 2.5.

**Note.** Males and females were matched because both have a dusky patch on the venter of the abdomen (Fig. 229) and because both have the same wide distribution. Males are much less common in collections than females.

**Variation.** Total length of females 8.0 to 11.0 mm. Females and male from Mato Grosso, Brazil, differed from those of other regions: the female epigynum is more rounded posteriorly and in posterior view there is a round depression ventrally, but the lateral and median sclerites are of the same width as the one illustrated (Fig. 227). The male from Mato Grosso has a more elongate median apophysis, and the two parallel prongs of the embolus are of similar width.

Illustrations were made from a female from Pipeline Road, Panama, and a male from Barro Colorado Island, Panama.

**Diagnosis.** The abdomen is elongate oval (Fig. 228). _Metazygia laticeps_ female has a pointed, wide, triangular epigynum (Fig. 226) with the posterior median plate slightly narrower than the lateral plates on each side (Fig. 227). The male has a large, semicircular median apophysis (at 5 hr in Fig. 230).

**Natural History.** Females are collected in tropical forest by unrolling rolled-up leaves, their retreat, at a height of about 150 cm. Specimens from Mato Grosso all came from gallery forest; Guyanas from forest savanna and swamp forest; and near Iquitos, Peru, from rain forest.

**Distribution.** Panama to Rio de Janeiro and northern Bolivia (Map 3F).

**Specimens Examined.** PANAMA Colón: Fort Sherman, 1♂ (MCZ). Panamá: nr. Gamboa, edge of Canal, 1♀ (W. Eberhard, MCZ); Soberania Natl. Park, Pipeline Road, 8 km NW Gamboa, 1♀ (MCZ); Barro Colorado Isl., Lago Gatún, 2♀, 2♂, MCZ.
TRINIDAD Port of Spain, 1♂ (MCZ). GUYANA Canje Ikuruwa River 09°70'N, 57°50'W, 1♀ (AMNH). FRENCH GUIANA nr. Placer Tresor, Roura Mtns., 1♀ (MCZ); nr. Sauteru, Matouri, 1♀ (MCZ); COLOMBIA Satandar: Rio Suárez, 500–1,000 m, 1♀ (AMNH). PERU Loreto: Iquitos, 1♀ (AMNH); Explorada Lodge, 80 km NE Iquitos, 1♀ (FSCA). **Metazygia mundula** Strand

Figures 231–238; Map 3F

*Anura* (Metazygia) *mundula* Strand, 1915: 114.

Ten female, two male, and two immature syntypes from mud-dauber wasp nest, Joinville, Santa Ca- tarina State, Brazil, in SMF no. 4010, examined.

*Metazygia mundula*—Roewer, 1942: 848.

*Larinia mundula*—Bonnet, 1957: 2350.

**Note.** Strand (1915: 114) wrote, "Since there is no certainty from the literature as to which species the specimens belong, I make some descriptive remarks and pro- pose, if necessary, the name *mundula*."

**Description.** Female syntype. Carapace orange, cephalic region darker. Chelicer- ae, labium, endites dark orange. Sternum orange. Coxae, legs orange. Dorsum of ab- domen light with a pair of dark anterior patches and four pairs of dark lines (Fig. 236). Venter light. Posterior median eyes same diameter as anterior medians, lat- erals 0.8 diameter. Anterior median eyes 0.5 diameter apart, 0.9 diameter from lat- erals. Posterior median eyes 0.3 diameter apart, 2.1 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 5.9 mm. Carapace 2.8 mm long, 2.1 wide, 1.4 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.6, metatarsus 1.8, tarsus 0.8. Second patella and tibia 2.3 mm, third 1.4, fourth 2.0.

Male syntype. Color, including marks on abdomen, as in female. Posterior med- ian eyes 0.9 diameter of anterior medians, laterals 0.5 diameter, posterior laterals 0.5. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.2 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. Second tibia as thick as first, with macro- setae. Total length 4.5 mm. Carapace 2.4 mm long, 2.0 wide, 0.9 wide behind lateral eyes. First femur 2.1 mm, patella and tibia 2.7, metatarsus 1.9, tarsus 0.7. Second pa- tella and tibia 2.3 mm, third 1.3, fourth 1.8.

**Note.** The syntypes have lost all white pigment and also the silver pigment of the eyes, perhaps from having been in a buf- fered formaldehyde solution (Levi, 1989). All except for one specimen (Figs. 231, 232) have the epigynum broken. Each side is broken off (Figs. 234, 235), apparently the result of mating. Males and females were collected together.

**Diagnosis.** The epigynum, unlike that of *M. genialis* (Fig. 239), has a concave margin on each side and a flat scape (Figs. 231, 233). In posterior view, it has a ventral pocket on each side (at 11 hr and 2 hr in Fig. 232). The male palp, like that of *M. genialis* (Figs. 243, 244), has a lobe on the tegulum (at 12 hr in Figs. 237, 238) but differs in the shape of the embolus lamella and median apophysis (center and at 5 hr in Fig. 237).

**Natural History.** All specimens came from a mud-dauber wasp nest.

**Metazygia genialis** (Keyserling)

Figures 239–246; Map 3F

*Epeira genialis* Keyserling, 1892: 156, pl. 8, fig. 114, 15. Two female syntypes from Rio Grande do Sul, Brazil, one has the epigynum broken, the other covered by secretions, in BMNH, examined.

*Epeira mundula*—Keyserling, 1892: 179, pl. 9, fig. 132, 5 (not female lectotype).

*Aranea genialis*—Roewer, 1942: 843.

*Ananura genialis*—Bonnet, 1955: 507.

**Note.** The male paralectotype of *E. mundula* belongs with the female of *M. genialis*.

**Description.** Female from Santa Vitória do Palmar, Rio Grande do Sul. Cephalic region of carapace dark brown, thoracic region yellowish. Chelicerae dark brown. Labium, endites dark brown. Sternum light brown. Coxae yellowish; legs with proxi-

**Abbreviations.** C, conductor; H, hematodocha; E, embolus; L, embolus lamella; M, median apophysis; P, paracymbium; R, radix; T, tegulum; Y, cymbium.

**Scale lines.** 1.0 mm, genitalia 0.1 mm.

M. genialis. Male from Santa Vitória do Palmar, Rio Grande do Sul. Color as in female, but cephalic region yellowish. Posterior me-
dian eyes 0.5 diameter of anterior medians, laterals 0.5 diameter. Anterior median eyes 0.4 diameter apart, 0.5 diameter from laterals. Posterior medians 0.2 their diameter apart, 2.2 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Third femur with three short macrosetae; each only three times as long as wide. Total length 4.8 mm. Carapace 2.6 mm long, 2.2 wide, 1.1 behind lateral eyes. First femur 2.2 mm, patella and tibia 2.7, metatarsus 2.2, tarsus 0.7. Second patella and tibia 2.4 mm, third 1.4, fourth 1.7.

Note. Males and females were collected together.

Variation. Total length of females 6.3 to 7.7 mm, males 4.8 to 5.8. Illustrations were made from Santa Vitória, Rio Grande do Sul, Brazil.

Diagnosis. The epigynum has a knob (Figs. 239, 240) rather than a flat scape as in *M. mundulella* (Figs. 231–235). The male, like *M. mundulella* (Figs. 237, 238), has a tegulum (T in Fig. 245) with a lobe (at 12 hr in Figs. 243, 245) and a distinctive shape of the embolus lamella (L in Fig. 245) and median apophysis (at 5 hr in Fig. 243).

Distribution. Bahia to Rio Grande do Sul States, Brazil (Map 3F).

**Metazygia amalla** new species

Figures 247–249; Map 3D

Holotype. Female holotype from Pinhal, Est. Santa Catarina, Brazil, Jan. 1948 (A. Maller), in AMNH. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange, cephalic region orange-brown. Chelicerae dark orange-brown. Labium, endites brown. Sternum orange. Coxae light orange, legs orange-brown. Dorsum of abdomen with faint dark markings forming outline of a folium (Fig. 249); venter light dusky. Posterior median eyes 0.5 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1.1 diameters from laterals. Posterior median eyes 0.2 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 6.3 mm. Carapace 2.7 mm long, 2.1 wide, 1.1 behind lateral eyes. First femur 2.4 mm, patella and tibia 2.7, metatarsus 1.8, tarsus 0.8. Second patella and tibia 2.3 mm, third 1.5, fourth 2.0.

Variation. Total length of females 6.3 to 6.5 mm. Illustrations were made from the female holotype. The holotype and paratype have the median area of the epigynum broken (Figs. 247, 248).

Diagnosis. *Metazygia amalla* differs from other species by the wide posterior median plate of the epigynum (Fig. 248).

**Metazygia ikuruwa** new species

Figures 250–252; Map 3D

Holotype. Male holotype from Canje Ikuruwa River, 05°30’N, 57°50’W, Guyana, Aug.–Dec. 1961 (G. Bentley), in AMNH. The specific name is a noun in apposition after the type locality.

Description. Male holotype. Carapace orange. Chelicerae, labium, endites orange; sternum, coxae orange. Legs orange, distal articles darker. Dorsum of abdomen with dark outline of folium (Fig. 252); venter dusky. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 4.4 mm. Carapace 2.4 mm long, 1.7 wide, 0.8 wide be-
hind lateral eyes. First femur 2.3 mm, patella and tibia 2.7, metatarsus 2.0, tarsus 0.9. Second patella and tibia 2.3 mm, third 1.3, fourth 1.9.

Diagnosis. This species differs from *M. gregalis* by the large anchor-shaped median apophysis (at 5 hr in Fig. 250).

Paratypes. GUYANA Bartica: Kartabo, 1920, 3♂ (CUC).

**Metazygia gregalis** (O. P.-Cambridge) Figures 253–262; Map 3E

*Epeira gregalis* O. P.-Cambridge, 1889: 22, pl. 5, fig. 3, ♀. Ten female syntypes from Veragua [Prov. Veraguas], Panama in BMNH, examined. Keyserling, 1892: 177, pl. 9, fig. 131, ♂, ♀.

*Metazygia similis* Caporiacco, 1947: 25; 1948: 660, fig. 70, ♀. Female holotype from Mackenzie, [06°00'N, 58°17'W], Guyana, in MZUF, examined. Brignoli, 1983: 274. NEW SYNONYMY.

**Synonymy.** The genitalia of *Metazygia manni* and *M. similis* are similar to those of *M. gregalis*. No differences could be found.

**Description.** Female from Panama. Carapace orange, cephalic region brown. Chelicerae brown. Labium, endites, sternum orange. Coxae orange; legs orange. Dorsum of abdomen with dusky pattern over tiny white pigment spots (Fig. 257); venter light dusky without marks. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 1.5 diameters from laterals. Posterior median eyes 0.5 diameter apart. Height of clypeus equals 0.8 diameter of anterior median eye. Total length 8.0 mm. Carapace 3.5 mm long, 2.7 wide, 1.5 behind lateral eyes. First femur 2.7 mm, patella and tibia 3.2, metatarsus 2.4, tarsus 0.9. Second patella and tibia 2.9 mm, third 1.8, fourth 2.5.

Male from Panama. Color as in female. Posterior median eyes 0.7 diameter of anterior medians, anterior laterals 0.7 diameter, posterior laterals 0.6. Anterior median eyes 0.5 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart. Height of clypeus equals 0.6 diameter of anterior median eye. Fangs modified (Figs. 261, 262). Endite without tooth, palpal femur without facing tubercle. First coxa with very small hook. Second tibia thicker than first, without special macrosetae. Total length 5.0 mm. Carapace 2.9 mm long, 2.1 wide, 1.3 wide behind lateral eyes. First femur 2.4 mm, patella and tibia 2.8, metatarsus 2.1, tarsus 0.9. Second patella and tibia 2.3 mm, third 1.5, fourth 2.0.

**Note.** Males and females are commonly collected together.

**Variation.** Total length of females 6.2 to 9.6 mm, males 4.0 to 6.0. The largest male and female both came from Pelotas, Rio Grande do Sul State, Brazil. The epigynum is quite variable: sometimes the posterior two bulges are absent, sometimes there is a median bulge. The illustrations were made from specimens from Barro Colorado Island, Panama.

**Diagnosis.** The female epigynum in ventral view is wider than long (Figs. 253, 254); that of *M. benella* and *M. yobena* is longer than wide (Figs. 263, 270). The median apophysis (M) of the male palpus is a small hook (Figs. 258, 260); it is longer in *M. benella* (Fig. 267) and has a black wall in *M. yobena* (Fig. 274).

**Natural History.** Specimens have been collected from the following places: brush along fences, on houses, and eaves of a building in Costa Rica; on a building at night in Panama; on walls under light at night in Paraguay; in sweeping river vegetation in Bolivia; from a wasp nest in Surinam; and from rolled leaves in savanna, Depto. Beni, Bolivia.

**Distribution.** Nicaragua, Greater Antil-
les (except Jamaica), Tobago, south to Argentina (Map 3E).

**Specimens Examined.** NICARAGUA Bonanza (AMNH). COSTA RICA Heredia: Serapiquí (MCZ); La Selva (MCZ, USNM). CARTAGO: Turrialba (CAS). Puntarenas: Finea Selva Verde (DU). PANAMA Chiriquí: Puerto Armuelles (FSCA); David (AMNH, MCZ). Veraguas: NE Puerto Mutis (MIUP). Herrera: París (MCZ). Colect: Natá (AMNH). **Metazygia benella** new species

**Figures** 263–269; Map 3C

**Holotype.** Female holotype, male paratype from near Cali, Valle, Colombia, ?1983 (W. Eberhard), in MCZ. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace light orange, cephalic region darker orange. Chelicerae orange-brown. Labium, endites dark orange. Sternum light orange. Cocae, legs light orange. Dorsum of abdomen white (Fig. 266); venter light dusky. Posterior median eyes 0.8 diameter of anterior medians, anterior laterals 0.8 diameter, posterior laterals 0.7. Anterior median eyes 0.7 diameter apart, 1.3 diameters from laterals. Posterior median eyes 0.2 diameter apart, 2.8 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 5.6 mm. Carapace 2.9 mm long, 2.3 wide, 1.5 wide behind lateral eyes. First femur 2.5 mm, patella and tibia 2.9, metatarsus 2.1, tarsus 1.0. Second patella and tibia 2.7 mm, third 1.3, fourth 2.3.

**Male paratype.** Color as in female. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.7 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Fangs modified (Fig. 269). Endite lacks tooth. Total length 5.0 mm. Carapace 2.5 mm long, 2.1 wide, 1.0 behind lateral eyes 1.0 wide. First

Figures 263–269. *M. benella* n. sp. 263–266, female. 263–265, epigynum. 263, ventral. 264, posterior. 265, lateral. 266, dorsal. 267–269, male. 267, male palpus. 267, mesal. 268, ventral. 269, eye region, chelicerae, and right palpus.

**Abbreviations.** C, conductor; E, embolus; M, median apophysis; R, radix.

**Scale lines.** 1.0 mm, genitalia 0.1 mm.
femur 2.1 mm, patella and tibia 2.5, meta-
tarsus 2.0, tarsus 0.9. Second patella and 
tibia 2.3 mm, third 1.3, fourth 1.8.

Note. Males and females were collected 
together.

Variation. Most individuals have a fo-
lium pattern on the abdomen as in Figure 
257. Total length of females 6.3 to 8.4 mm, 
male 4.2 to 5.1. Illustrations were made of 
the female holotype and male paratype 
collected with it.

Diagnosis. The female epigynum (Fig. 
263) is longer than wide, lacks the posterior 
notch present in M. yobena (Fig. 270), and 
has a pair of lobes on the scape (at 10 hr 
and at 2 hr in Fig. 263). The male has a 
round tubercle on the tegulum (at 1 hr in 
Fig. 267), has a longer median apophysis 
(at 4 hr in Fig. 267) than M. gregalis (Fig. 
258, M in Fig. 260), and is without the 
black posterior wall (Fig. 267) present in 
M. yobena (at 4 hr in Fig. 274).

Natural History. A male and female 
were collected in roadside shrubs at night 
early near Cali, Colombia.

Distribution. Panama and Colombia 
(Map 3C).

Paratypes. COLOMBIA Valle: nr. Cali, 
1,000 m, no date, 2♀ (W. Eberhard 759, 
807, MCZ), 8 May 1973, 1♂ (W. Eberhard 
513, MCZ), Feb. 1975, 1♀ (W. Eberhard 
937, MCZ), 1973–1974, 1♂ (W. Eberhard, 
Eberhard, MCZ); above Barrio Siloe, SW 
Cali, 3 July 1972, 1♂ (M. Corn, MCZ).

Specimens Examined. PANAMA Panamá: Barro 
Colorado Island, Lago Gatún, 25 Apr. 1946, 1♀ (T. 
C. Schneirla, AMNH), July 1950, 1♀; 19 July 1954, 
1♀, 1♂; 14–18 Jan. 1958, 2♀; 6 Feb. 1958, 
1♀, 1♂; 18 Feb. 1958, 1♂ (A. M. Chickering, MCZ).

Metazygia yobena new species 
Figures 270–276; Map 3C

Holotype. Female holotype, one female, and two male 
paratypes from Mitú, 185 m, Depto. Vaupés, Co-

lombia, at night in bamboo, 20 Apr. 1979 (M. Bar-
reto), in MCZ. The specific name is an arbitrary 
combination of letters.

Description. Female from Cuyabeno, 
Sucumbios Prov., Ecuador. Carapace 
brownish black, sides of thoracic region 
light orange. Chelicerae black. Labium, 
endites brown. Sternum yellowish, darker 
on each side. Coxae, legs dusty orange. 
Dorsum of abdomen with indistinct me-
dian lighter band (Fig. 273); venter dark 
dusky. Posterior median eyes 0.9 diameter 
of anterior medians, laterals 0.7 diameter. 
Anterior median eyes 0.8 diameter apart. 
1.3 diameters from laterals. Posterior me-
dian eyes 0.2 diameter apart. 2.5 diameters 
from laterals. Height of clypeus equals 0.7 
diameter of anterior median eye. Total 
length 6.0 mm. Carapace 3.1 mm long, 2.2 
wide, 1.3 wide behind lateral eyes. First 
femur 2.5 mm, patella and tibia 3.2, meta-
tarsus 2.3, tarsus 1.1. Second patella and 
tibia 2.7 mm, third 1.6, fourth 2.3.

Male paratype. Color as in female. Post-
erior median eyes 0.7 diameter of anterior 
medians, laterals 0.7 diameter. Anterior 
median eyes 0.7 diameter apart. 0.7 di-
ameter from laterals. Posterior median eyes 
0.3 diameter apart, 1.9 diameters from lat-
erals. Height of clypeus equals 0.6 diam-
eter of anterior median eye. Fangs mod-
ified (Fig. 276). Endite without tooth, pal-
pal femur without facing tubercle. First 
coxa with small hook on its side. All legs 
with relatively long macrosetae. Total 
length 5.2 mm. Carapace 2.7 mm long, 2.1 
wide, 1.1 wide behind lateral eyes. First 
femur 2.4 mm, patella and tibia 2.9, meta-
tarsus 2.1, tarsus 0.9. Second patella and 
tibia 2.4 mm, third 1.5, fourth 2.0.

Note. Males and females were collected 
together.

Variation. Total length of females 4.9 
to 7.5 mm, males 4.1 to 5.6. Most females 
have the folium pattern made up of pairs 
of brackets on the abdomen, which is typi-
ical of the genus (Fig. 257). Some male 
palpi have only a small tubercle or none 
on the tegulum of the palpus (at 1 hr in 
Fig. 274). Illustrations were made from a 
specimen from the Cuyabeno Reserve, 
Sucumbios Prov., Ecuador, and from a pal-
pus from a male collected in Depto. Vaup-
és, Colombia. Figure 276 was made from 
a specimen from near Manaus, Brazil.
**Diagnosis.** The epigynum (Fig. 270) differs from that of *M. gregalis* (Fig. 253) by being longer than wide and from that of *M. benella* (Fig. 263) by having a notch on the posterior margin (at 6 hr in Fig. 270). The palpus differs from that of the two similar species by having a black hook on the hook-shaped median apophysis of the palpus (at 4 hr in Fig. 274).

**Natural History.** Specimens came from bamboo in Colombia; from trees in a lake in the Cuyabeno Reserve, Ecuador; from trees in rain forest; from swamp plants in Peru; from forest savanna in Guyana; from falling into a canoe from overhanging vegetation in Venezuela; and from cerrado shrub in Mato Grosso, Brazil.

**Distribution.** Guyana and Amazon drainage (Map 3C).

**Paratypes.** COLOMBIA Vaupés: Mitú, at night in bamboo, 20 Apr. 1971, 1♀, 1♂ (M. Barreto, MCZ).

Specimens Examined. VENEZUELA AMAZONAS: middle Río Baria, 100 m (AMNH); GUYANA Ku-yuwini River, from landing to Essequibo (AMNH); Upper Essequibo River (AMNH); Canje Ikuruwa River (AMNH); Kartabo (AMNH); Tumatumari (AMNH). Beni, 14°47'S, 66°15'W (USNM); 19.5 km S Rurrenabaque (USNM).

**Metazygia voluptifica** (Keyserling)

Figures 277–284; Map 3D

**Epeira voluptifica** Keyserling, 1892: 152, pl. 7, fig. 112, 3♀, 3♂. Female and male syntypes from Rio Grande [do Sul], Brazil, in BMNH, no. 1890.7.1.5041–5042, examined.

**Epeira mundula** Keyserling, 1892: 179, pl. 9, fig. 132, 4♀, not 3♂. Female lectotype, here designated, from Rio Grande do Sul, Brazil, in BMNH, no. 1890.7.1.5067, 5068, examined. NEW SYNONYM.

**Zilla punctata** Keyserling, 1893: 305, pl. 15, fig. 225, 1♀. Female holotype from Novo Friburgo, Brazil, lost. Not in BMNH, HECO, MCZ, NMW, USNM, ZMB. NEW SYNONYM.

**Aranea voluptifica:**—Roewer, 1942: 856.

**Araneus voluptificus:**—Bonnet, 1955: 631.

**Note.** Keyserling described this species several times, first as *Epeira voluptifica*. Keyserling's female has a bracket folium as in *M. gregalis* (Fig. 257) and the epigynum lacks a scape. The type vial of *Epeira mundula* has a toothed, blue-bordered, 23–30-mm label of Keyserling reading, "Rio Grande do Sul, *Epeira mundula* Keys." The female is chosen as the lectotype because Keyserling's illustration of the female is recognizable while that of the male is not. The female lectotype has the shape of the epigynum torn off, as is that of most specimens. The male in the type vial is one that I associated with *M. genalis*. A second vial of *E. mundula* with a female syntype has a similar label, 20 by 30 mm in size, and has also a different label with the number 1889.2.17. It also contains my typed label reading "♀, 3♂ syntypes," added in 1974, when I examined the specimens and illustrated them. The type of *Zilla punctata* is lost, but the illustration of the epigynum matches this species. Keyserling gives the total length as 9.0 mm, larger than specimens I have examined.

**Description.** Female from Guaíba, Rio Grande do Sul. Carapace light orange, cephalic area darker. Chelicerae brown. La-
bium, endites orange. Sternum light orange; Coxae light orange; legs light orange, distal articles darker, dusky. Dorsum of abdomen with a pattern of paired lines or brackets (Fig. 282); venter with some white pigment behind epigynum. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.3 diameter apart, 1 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.6 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 5.0 mm. Carapace 2.1 mm long, 1.6 wide, 0.9 wide behind lateral eyes. First femur 1.9 mm, patella and tibia 2.1, metatarsus 1.4, tarsus 0.7. Second patella and tibia 1.9 mm, third 1.1, fourth 1.6.

Male from Santa Vitória do Palmar. Color as in female, but less gray pigment on abdomen. Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.7 their diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.3 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Second tibia thinner than first. Total length 4.5 mm. Carapace 2.1 mm long, 1.6 wide, 0.9 wide behind lateral eyes. First femur 2.2 mm, patella and tibia 2.7, metatarsus 2.0, tarsus 0.8. Second patella and tibia 2.4 mm, third 1.2, fourth 1.5.

Note. Males and females were matched because collections came from the same locality (Minas Serinha, Minas Gerais) and because the carapace was of similar length. The female from Mato Grosso was collected with a male M. corumba; the E. mundula lectotype was with a male M. genialis. However, Keyserling described the female of E. voluptifica together with a male that I consider here the correct match.

Variation. Most females have the scape torn off (Figs. 280, 281). Total length of females 4.8 to 7.3 mm, males 4.0 to 5.5. Illustrations of females were made from specimens from Guaiaba, Rio Grande do Sul; the male from Santa Vitória do Palmar, Rio Grande do Sul.

**Diagnosis.** The female can be separated from others by the two almost round circles of the epigynum in ventral view (Figs. 277, 280). The female is distinguished from that of *M. viriosa* by the posterior median plate of the epigynum, which is slightly wider than each lateral plate (Figs. 278, 281). The male is separated from others by the black fold of the tegulum of the palpus, which is distally serrate (T at 12 hr in Fig. 283).

**Natural History.** A female was collected from grass and brush along a fence in Colombia.

**Distribution.** Colombia to Argentina (Map 3D).

**Metazygia viriosa** (Keyserling), new combination

**Figures 285–288; Map 3A**

**Epithea viriosa** Keyserling, 1892: 165, pl. 8, fig. 122.

**Aranea viriosa** — Roewer, 1942: 556.

**Araneus viriosus**: — Bonnet, 1955: 630.

**Description.** Female holotype. Carapace orange-brown, cephalic region darkest. Chelicerae, labium, endites brown. Sternum dusky orange. Legs light orange. Dorsum of abdomen with anterior transverse black band (Fig. 288). Venter without marks or pigment. Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes
0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. Abdomen spherical (Fig. 288). Total length 4.8 mm. Carapace 1.7 mm long, 1.3 wide. First femur 1.7 mm, patella and tibia 2.1, metatarsus 1.4, tarsus 0.6.

Second patella and tibia 1.8 mm, third 1.1, fourth 1.7.

Variation. All females had the scape of the epigynum torn off. Total length of females 4.6 to 5.4 mm. Illustrations were made from the female holotype; Figure 287 was made from a female from Juru-batuba.
Diagnosis. *Metazygia viriosa* differs from *M. voluptifica* by the markings of the abdomen (Fig. 288) and by the median posterior depression of the epigynum (Fig. 286).

*Metazygia ituari* new species

Figures 289–291; Map 3D

Holotype. Female holotype from Utiariti (Utiariti), Est. Mato Grosso, Brazil, 1961 (H. Lenko) in MZSP no. 4155. The specific name is an arbitrary combination of letters.

Description. Female holotype. Cephalothorax light orange, only eyes with some black pigment. Dorsum of abdomen with three longitudinal white pigment bands (Fig. 291); venter with white pigment spots. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.6 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.8 diameters from laterals. Ocular quadrangle narrower behind than in front. Height of clypeus equals 0.4 diameter of anterior median eye. Abdomen (Fig. 291). Total length 3.1 mm. Carapace 1.3 mm long, 1.1 wide, 0.6 wide behind lateral eyes. First femur 1.1 mm, patella and tibia 1.2, metatarsus 0.7, tarsus 0.5. Second patella and tibia 1.1 mm, third 0.7, fourth 0.9.

Diagnosis. The female, which apparently has lost the scape of her epigynum, is separated from *M. voluptifica* and *M. viriosa* by the short, wide posterior median plate of the epigynum (Fig. 290).

*Metazygia limonal* new species

Figures 292–294; Map 4A

Holotype. Female holotype from El Limonal, Alto Río Madre de Dios, Depto. Madre de Dios, night collecting, 21 June 1988 (P. Lozada), in MUSM. The specific name is a noun in apposition after the type locality.

Description. Female holotype. Carapace very light orange, black only between eyes. Chelicerae, labium, endites light orange. Sternum light orange. Legs light orange. Dorsum of abdomen white with anterior dumbbell-shaped black marks (Fig. 294); venter with a white square. Posterior median eyes same diameter as anterior medians, anterior laterals 0.7 diameter, posterior 0.6. Anterior median eyes 0.7 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Ocular quadrangle narrower behind than in front. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.2 mm. Carapace 1.7 mm long, 1.3 wide, 0.8 behind lateral eyes. First femur 1.9 mm, patella and tibia 2.4, metatarsus 1.7, tarsus 0.7. Second patella and tibia 2.1 mm, third 1.2, fourth 1.8.

Variation. All females examined had the scape of the epigynum torn off (Figs. 292, 293). Total length of females 3.0 to 4.2 mm. Illustrations were made from the female holotype.

Diagnosis. *Metazygia limonal* differs from others by the Y-shaped posterior median plate of the epigynum (Fig. 293).

Distribution. From Depto. Madre de Dios, Peru, to northern Argentina (Map 4A).

*Metazygia tanica* new species

Figures 295–297; Map 4A

Holotype. Male holotype from Botanical Gardens, Georgetown, Guyana, 22 Feb. 1959 (A. Nadler), in AMNH. The specific name is an arbitrary combination of letters.

Description. Male holotype. Cephalothorax orange, sternum lighter. Dorsum of abdomen light with faint dusky outline of folium (Fig. 297); venter light. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.3 diameters from later-
als. Height of clypeus equals 0.8 diameter of anterior median eye. Endite with minute tooth. Total length 4.2 mm. Carapace 2.5 mm long, 1.9 wide, 0.9 behind lateral eyes. First femur 2.3 mm, patella and tibia 2.7, metatarsus 2.0, tarsus 0.9. Second patella and tibia 2.4 mm, third 1.5, fourth 2.0.

**Diagnos**ts. This male differs from *M. voluptifica* by having a structure (embolus or embolus lamella) of the palpus in a diagonal position with its sides almost parallel (Fig. 295).

**Metazygia vaupes** new species

**Figures** 298–302; **Map** 4A

**Holotype.** Female holotype from Mitú, Depto. Vaupés, 200 m, Colombia, Feb. 1975 (P. A. Schnelle), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace yellowish. Chelicerae, labium, endites yellowish. Sternum yellowish. Legs yellowish. Dorsum of abdomen without color but with white pigment spots around anterior and sides (Fig. 301); venter with white pigment spots. Posterior median eyes 1.2 diameters of anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart, 0.8 diameter from laterals. Ocular quadrangle square. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 3.1 mm. Carapace 1.17 mm long, 1.04 wide, 0.54 behind lateral eyes. First femur 1.52 mm, patella and tibia 1.82, metatarsus 1.35, tarsus 0.48. Second patella and tibia 1.53 mm, third 0.87, fourth 1.26.

Male from Depto. Loreto, Peru. Color as in female but anterior white band of abdomen less distinct. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Ocular quadrangle narrower behind than in front. Height of clypeus equals 0.6 diameter of anterior median eye. First coxa with small hook. Second tibia thicker than first, with one long macroseta and several short ones distally, all in one line. Total length 2.0 mm. Carapace 1.2 mm long, 0.9 wide, 0.4 wide behind lateral eyes. First femur 1.4 mm, patella and tibia 1.7, metatarsus 1.2, tarsus 0.5. Second patella and tibia 1.3 mm, third 0.7, fourth 1.0.

**Note.** Males and females were collected in the same location in Rondônia, and both lack dark pigment dorsally on the abdomen.

**Variation.** Total length of females 3.1 to 3.2 mm. Illustrations were made from the female holotype and a male from Rondônia.

**Diagnosis.** The abdomen appears heart-shaped (Fig. 301). The epignyum is very distinct with a short rounded scape (Figs. 298, 299). The male has a shorter, smaller embolus lamella (Fig. 302) than *M. castaneoscutata* (Fig. 308).

**Natural History.** Specimens have been collected in grass and shrubs in Loreto, Peru, and rain forest in Rondônia, Brazil.

**Distribution.** Amazon region (Map 4A).

**Metazygia castaneoscutata** (Simon)

**Figures** 303–308; **Map** 4B

*Araneus castaneoscutatus* Simon, 1895: 806. Female holotype from Amazonas [specimen labeled as coming from Iquitos to Pebas, Peru], in MNHN, examined. Bonnet, 1955: 452.

*Aranea castaneoscutata*—Roewer, 1942: 838.

**Description.** Female holotype. Carapace light orange with a median black band. Chelicerae black. Labium, endites, sternum light orange. Legs dusky orange. Dorsum of abdomen with black band around anterior, continuing around sides of abdomen and meeting black ring around spinnerets (Figs. 306, 307); a narrow band of white pigment spots parallel to band on dorsum and a median dorsal dusky patch.
Venter with a dusky T-shaped mark and a black ring around spinnerets (Fig. 307). Posterior median eyes 0.7 diameter of anterior medians, laterals 0.5 diameter. Anterior median eyes 0.3 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.2 diameter apart, 0.8 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 3.4 mm. Carapace 1.2 mm long, 1.0 wide, 0.5 wide behind lateral eyes. First femur 1.3 mm, patella and tibia 1.5, metatarsus 1.0, tarsus 0.4. Second patella and tibia 1.3 mm, third 0.7, fourth 1.1.

Male from Alto Rio Comaina. Color as in female. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.2 diameter apart, almost touching laterals. Posterior median eyes 0.2 diameter apart, 0.8 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Fourth coxa with a tiny macroseta on left side only. Second tibia thicker than first, both first and second with macrasetae. Total length 2.1 mm. Carapace 1.2 mm long, 0.9 wide, 0.5 behind lateral eyes. First femur 1.1 mm, patella and tibia 1.3, metatarsus 0.8, tarsus 0.4. Second patella and tibia 1.1 mm, third 0.6, fourth 0.8.

Note. Males and females were matched because of similar color and markings and because they were collected together.

Variation. The scope of the epigynum may be broken off (Fig. 304). Total length of females 3.1 to 4.5 mm, males 2.1 to 2.3. Illustrations were made from a female from the Tambopata Reservation and a male from Alto Rio Comaina.

Diagnosis. *Metazygia castaneoscutata* can be separated from others by the spherical abdomen (Fig. 306) and its coloration. The epigynum has a longer scape (Fig. 303) than *M. vaupes* (Fig. 298) and a differently shaped posterior median plate (Fig. 305). The male has a longer embolus lamella (at 10 hr in Fig. 308) and more distinct conductor (center of Fig. 308) than *M. vaupes* (Fig. 302).

Natural History. Specimens came from forest interior near Manaus.

Distribution. Amazon region (Map 4B).

*Metazygia octama* new species

Figures 309–313; Map 4B

Holotype. Female holotype from near Cali, 1,000 m elev., Depto. Valle, Colombia (W. Eberhard, no. 821), in MCZ. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange, eye region black, thoracic region lightest. Chelicerae, labium, endites orange. Sternum orange. Legs orange. Abdomen white with a black band around anterior (Fig. 312), venter with a white square between epigynum and spinnerets. Posterior median eyes 0.9 diameter of anterior medians, laterals 0.5 diameter. Anterior median eyes 0.6 diameter apart, 0.4 diameter from laterals. Posterior median

---

Scale lines. 1.0 mm, genitalia 0.1 mm.
eyes 0.3 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 5.5 mm. Carapace 2.1 mm long, 1.6 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.5, metatarsus 2.0, tarsus 0.7. Second patella and tibia 2.3 mm, third 1.4, fourth 2.0.

Male from type locality. Color as in female. Carapace with slight lobe. Posterior median eyes same diameter as anterior medians, anterior laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.1 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Third and fourth coxa each with one long macrosetae. Second tibia thicker than first, with several large macrosetae. Total length 3.7 mm. Carapace 1.6 mm long, 1.3 wide, 0.5 wide behind lateral eyes. First femur 1.7 mm, patella and tibia 2.2, metatarsus 1.7, tarsus 0.6. Second patella and tibia 1.5 mm, third 1.0, fourth 1.5.

Note. Males and females were collected together.

Variation. Total length of females 4.1 to 5.1 mm, males 3.1 to 3.7. Illustrations were made from the female holotype and a male paratype.

Diagnosis. Metazygia octama females have a thicker epigynal scape (Figs. 309, 310) than M. vaupes (Fig. 298) and M. castaneoscutata (Fig. 303). In males the palpus has a hair-like, S-shaped embolus that lies between the transparent lamella and conductor (between center and at 11 hr in Fig. 313).

Natural History. A female and immatures were collected at night on a roadside shrub near Cali, Colombia. When living they were dark green with reddish first pair of legs.

Distribution. From Panama to Depto. Madre de Dios, Peru (Map 4B).

Metazygia floresta new species
Figures 314–317; Map 4B

Holotype. Female holotype from Floresta dos Macacos, Est. Guanabara [Est. Rio de Janeiro], Brazil, Feb. 1961 (M. Alvarenga), in AMNH. The specific name is a noun in apposition after the type locality.

Description. Female holotype. Carapace orange, eye region black. Chelicerae brown. Labium, endites dusky orange. Sternum orange. Legs orange. Dorsum of abdomen white with a dark band around the anterior (Fig. 317). Venter with a large white square between epigynum and spinnerets. Eyes large. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 3.8 mm. Carapace 1.5 mm long, 1.0 wide, 0.5 behind lateral eyes. First femur 1.6 mm, patella and tibia 1.9, metatarsus 1.3, tarsus 0.5. Second patella and tibia 1.6 mm, third 0.9, fourth 1.3.

Diagnosis. Abdomen subspherical, flatter anteriorly, and slightly pointed posteriorly (Fig. 317). This female differs from all others in the smooth, sclerotized scape (Figs. 314–316) with fused plates in posterior view (Fig. 315).

Metazygia mariaheleinae new species
Figures 318–321; Map 4C

Holotype. Male holotype from Reserva Ducke, Manaus, Est. Amazonas, Brazil, Aug. 1971 (M. E. Galiano), in MACN. The species is named after the collector.

Description. Male holotype. Carapace light orange, eye region dusky. Chelicerae

dusky. Labium, endites dusky. Sternum dusky light orange. Legs light orange, distally dusky. Dorsum of abdomen white with black band around anterior (Fig. 320). Venter with white longitudinal band on each side of genital furrow (Fig. 321). Posterior median eyes 0.8 diameter of anterior medians, anterior laterals 0.7 diameter, posterior 0.5. Anterior median eyes their diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.4 diameter apart, their diameter from laterals. Ocular quadrangle narrower behind than in front. Height of clypeus equals 0.6 diameter of anterior median eye. Fourth coxa with short macroseta. Second tibia thicker than first, with three to four strong macrosetae on distal quarter. Total length 2.8 mm. Carapace 1.4 mm long, 1.1 wide, 0.5 behind lateral eyes. First femur 1.5 mm, patella and tibia 2.0, metatarsus 1.5, tarsus 0.5. Second patella and tibia 1.4 mm, third 0.9, fourth 1.3.

**Diagnosis.** The male is distinguished by an embolus that points clockwise (center of Fig. 318) and a median apophysis that is rectangular in ventral view (at 3 hr in Fig. 318).

*Metazygia nigrocincta* (F. P.-Cambridge), new combination

Figures 322–327; Map 4G

*Aranea nigrocincta* F. P.-Cambridge, 1904: 513, pl. 49, figs. 11, 12, ‡, ‡. Female and male syntypes from Bugaba, Panama, in BMNH, lost. Roewer, 1942: 848.

The types are lost. F. P.-Cambridge's illustration fits this species.

**Description.** Female from Fortín de los Flores, Veracruz, Mexico. Carapace orange, eye region black. Chelicerae dark brown. Labium, endites dark dusky orange. Sternum dusky orange. Coxae orange; legs dark dusky on orange. Dorsum of abdomen white with a black band across anterior (Fig. 525); venter with a white square (Fig. 326). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.6 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.0 mm. Carapace 1.9 mm long, 1.4 wide, 0.7 behind lateral eyes. First femur 1.8 mm, patella and tibia 2.3, metatarsus 1.5, tarsus 0.6. Second patella and tibia 2.0 mm, third 1.2, fourth 1.7.

Male from Veracruz, Mexico. Color as in female. Carapace with small lobes. Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.2 diameters from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. First coxa with large hook, third and fourth each with a short macroseta. Total length 2.7 mm. Carapace 1.4 mm long, 1.2 wide, 0.6 behind lateral eyes. First femur 1.6 mm, patella and tibia 1.8, metatarsus 1.2, tarsus 0.5. Second patella and tibia 1.5 mm, third 0.9, fourth 1.3.

**Note.** Males and females were collected together.

**Variation.** Total length of females 3.8 to 4.7 mm, males 2.5 to 2.7. Some males have macrosetae on the fourth coxae only, not on the third. Specimens from Jalisco, Mexico, have two white spots on the underside of the abdomen. Illustrations were made from specimens from Veracruz, Mexico.

**Diagnosis.** The female's abdomen is subspherical, widest anteriorly (Fig. 325). Females of this species are distinguished from those of *M. lagiana* (Figs. 328, 329) by having a thin, straight epigynal scape (Fig. 322) and a Y-shaped posterior median plate with openings at the end of the arms (Figs. 323, 328, 329). The male's palpus has an undulating median apophysis (Fig. 327) that is similar to that of *M. castaneoscutata* (Fig. 308) but is narrower at its base. The embolus lamella of this species (at 11 hr in Fig. 327) does not extend...
by beyond the clypeal tip as it does in M. castaneoscutata.

**Distribution.** Mexico to Panama (Map 4G).

**Metazygia lagiana** new species

**Figures 328–332; Map 4C**

**Holotype.** Female holotype from Cataratas de Iguaçu, Misiones Prov., Argentina, 5 Oct. 1963 (M. E. Galiano), in MACN. The species name is an arbitrary combination of letters.

**Description.** Female. Carapace shiny with head black grading into the orange sides of the thoracic region. Chelicerae, labium, endites dark brown. Sternum black. Coxae yellow; legs yellow with black ring around end of first tibiae. Dorsum of abdomen white, with black band around anterior and black spots posteriorly (Fig. 330); venter with black median band from pedicel to and enclosing spinnerets (Fig. 331). Posterior median eyes 1 diameter of anterior medians, anterior laterals 1 diameter, posterior 0.8. Anterior median eyes their diameter apart, 0.7 from laterals. Posterior median eyes 0.5 their diameter apart, 1.7 from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 4.0 mm. Carapace 1.5 mm long, 1.3 wide, 0.7 behind lateral eyes. First femur 1.5 mm, patella and tibia 1.9, metatarsus 1.2, tarsus 0.6. Second patella and tibia 1.6 mm, third 1.0, fourth 1.4.

Male paratype. Color differs from that of female: carapace orange with eye region black, sternum orange. Abdomen with anterior black band, venter with a wider than long white rectangle. Posterior median eyes 0.8 diameter of anterior medians, anterior laterals 0.5 diameter, posterior laterals 0.4. Anterior median eyes 0.8 diameter apart, 0.8 from laterals. Posterior median eyes 0.3 diameter apart, slightly more than one from laterals. First coxae with large hook on venter, third and fourth each with a macroseta. Second tibiae thicker than first with long macroseta almost in middle on venter. Total length 2.9 mm. Carapace 1.7 mm long, 1.4 wide. First femur 1.8 mm, patella and tibia 2.2, metatarsus 1.6, tarsus 0.6. Second patella and tibia 1.5 mm, third 0.9, fourth 1.4.

**Note.** Male and female were collected at the same locality.

**Variation.** Total length of females 3.7 to 4.0 mm.

**Diagnosis.** The female differs from that of M. nigrocincta by having an epigynal scape that is thin, bent, and transparent (Fig. 328) and a posterior median plate upside-down heart-shaped (Fig. 329). The male palpus features a knob-shaped median apophysis (at 4 hr in Fig. 332).

**Natural History.** A female has been collected in cerrado scrub in Mato Grosso, Brazil.

**Distribution.** Depto. Madre de Dios, Peru, to northern Argentina (Map 4C).

**Paratypes.** ARGENTINA **Misiones:** Gral. Belgrano, Jan. 1966, 1♀; Dec. 1972, 1♂ (M. E. Galiano, MACN).

---

*Scale lines.* 1.0 mm, genitalia 0.1 mm.

Metazygia carimagua new species
Figures 333–336; Map 4C

Holotype. Female holotype and one female paratype from Carimagua, 100 m. Depto. Meta, Colombia, Oct. 1973, grass and bushes along fence (W. Eberhard), in MCZ. The specific name is a noun in apposition after the type locality.

Description. Female holotype. Carapace orange. Chelicerae, labium, endites orange. Sternum, legs orange. Dorsum of abdomen white, with an indistinct pair of dusky patches anteriorly (Fig. 336). Venter with white transverse bar of white pigment spots behind epigynum. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.3 diameter apart, 0.9 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Total length 3.4 mm. Carapace 1.6 mm long, 1.2 wide, 0.7 behind lateral eyes. First femur 1.7 mm, patella and tibia 2.1, metatarsus 1.7, tarsus 0.6. Second patella and tibia 1.6 mm, third 0.9, fourth 1.4.

Diagnosis. The species lacks black pigment, even in the eye region (Fig. 336). The epigynum differs from that of other species by having a pentagonal shape in ventral view (Fig. 333) and a narrow posterior median plate (Fig. 334).

Specimen Examined. COLOMBIA Meta: Carimagua, 100 m, 1♀ (W. Eberhard 633, MCZ).

Metazygia loque new species
Figures 337–341; Map 4C

Holotype. Female holotype from Burrenahaque, Beni, Bolivia, Oct.–Nov. 1956 (L. Peña), in IRSNB. The specific name is an arbitrary combination of letters.

Description. Female holotype. Carapace orange-yellow, cephalic region dusky. Chelicerae brown. Labium, endites brown. Sternum dusky orange, borders darkest. Coxae, legs orange-yellow with distal articles darkest. Dorsum of abdomen with dense white pigment spots, anterior with black transverse band (Fig. 340); venter with a pair of white longitudinal bands and a pair of white spots on light gray (Fig. 341). Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.2 diameter apart, 0.9 diameter from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. Total length 4.5 mm. Carapace 1.7 mm long, 1.2 wide, 0.7 behind lateral eyes. First femur 1.9 mm, patella and tibia 2.3, metatarsus 1.6, tarsus 0.5. Second patella and tibia 2.0 mm, third 1.1, fourth 1.5.

Diagnosis. The abdomen is oval, widest in middle, and slightly flattened anteriorly (Fig. 340). The female is distinguished by having an epigynum that is flat, ventrally projecting, and longer than wide (Figs. 337–339).

Metazygia cienaga new species
Figures 342–345; Map 4D

Holotype. Female holotype from along Arroyo Frio, La Ciénaga, Prov. La Vega, 19°04'N, 70°51'W, Dominican Republic, 8 Jan. 1986 (S. Larcher), in USNM. The specific name is a noun in apposition after the type locality.

Description. Female holotype. Carapace orange, cephalic region black. Chelicerae, labium, endites orange. Sternum orange. Coxae orange, legs dusky orange. Dorsum of abdomen white with two anterior black marks that are fused ventrally above carapace (Fig. 345). Venter white, with large white square between epigynum and spinnerets. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.5 diameters from laterals. Height of clypeus equals 0.3 diameter of anterior median eye. Total length 5.2 mm. Cara-
pace 2.3 mm long, 1.7 wide, 0.9 behind lateral eyes. First femur 2.2 mm, patella and tibia 2.7, metatarsus 1.8, tarsus 0.8. Second patella and tibia 2.2 mm, third 1.4, fourth 1.9.

**Diagnosis.** The abdomen is oval, widest in middle, anteriorly flattened slightly with median protuberance (Fig. 345). The epigynum has a median, wide lobe (Fig. 342) and a triangular, posterior median plate (Fig. 343).

**Metazygia souza** new species
Figures 346–350; Map 4D

**Holotype.** Female holotype from Ilha de Maracá, Rio Uraricoera, Roraima State, Brazil, 25 Sept. 1987 (M. E. L. Souza), in MCN. no. 20059. The specific name is a noun in apposition after the collector.

**Description.** Female holotype. Carapace yellow, eye region black. Chelicerae dusky yellow. Labium, endites, sternum yellow. Coxae, legs yellow. Dorsum of abdomen with dense white pigment and a black band around the anterior (Fig. 349), sides and venter without pigment (Fig. 350). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.6 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.4 diameter apart, 1.3 diameters from laterals. Height of clypeus equals 0.2 diameter of anterior median eye. Total length 4.0 mm. Carapace 1.5 mm long, 1.2 wide, 0.6 behind lateral eyes. First femur 1.7 mm, patella and tibia 2.1, metatarsus 1.5, tarsus 0.6. Second patella and tibia 1.7 mm, third 1.0, fourth 1.5.

**Diagnosis.** Unlike that of other species, the epigynum of *M. souza* has a posterior median notch (Figs. 346, 347).

**Metazygia lopes** new species
Figures 351–359; Map 4D

**Holotype.** Female holotype and one female and six male paratypes from Hacienda Mozambique, 15 km SW Puerto Lopez, 500 m elev., Depto. Meta, Colombia (W. Eberhard), in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace, sternum, legs yellow; legs with tips of tarsi black. Dorsum of abdomen with white pigment and a dusky band that is broken in middle around anterior (Fig. 355). Venter white behind epigynum, with transverse dark mark in front of spinnerets (Fig. 356). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes a little less than their diameter apart, a little less than their diameter from laterals. Posterior median eyes 0.3 their diameter apart, 1.7 from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.2 mm. Carapace 1.7 mm long, 1.2 wide, 0.6 behind lateral eyes. First femur 1.8 mm, patella and tibia 2.1, metatarsus 1.7, tarsus 0.7. Second patella and tibia 1.7 mm, third 1.0, fourth 1.4.

Male paratype. Coloration as in female. Carapace shiny with indistinct round thoracic depression enclosing a median longitudinal mark. Posterior median eyes 1 diameter of anterior medians, laterals 0.8 diameter. Anterior median eyes their diameters apart, 0.5 from laterals. Posterior median eyes almost touching, 1.7 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. First coxae with small hook. Fourth coxae with a pointed tubercle. Abdomen oval, longer than wide. Total length 2.8 mm. Carapace 1.5 mm long, 1.1 wide, 0.5 behind lateral eyes. First femur 1.7 mm, patella and tibia 2.2, metatarsus 1.7, tarsus 0.7. Second patella and tibia 1.6 mm, third 0.9, fourth 1.2.

**Note.** Males and females have been collected together. The epigynum of some specimens is completely covered by amorphous hard material, probably placed there by the male after mating.

**Variation.** Total length of females 3.2 to 4.5 mm. Eberhard (personal communication) reports the species to be green when alive. Illustrations were made from the holotype and paratypes.

**Diagnosis.** The abdomen is spherical (Figs. 355, 356) and, unlike many species, the eye region of the carapace is light in color (Fig. 355) and the posterior median
plate of the epigynum is dumbbell-shaped (Fig. 352). The male has a tubercle on the fourth coxa and a complex-shaped conductor (C in Fig. 359) and a long, thorn-shaped embolus (E in Figs. 357–359).

**Natural History.** Specimens have been collected in grass and brush along a fence in Carimagua, Colombia; in grassland jungle at Puerto Lleras, Colombia; and in savanna, fogging trees, in Venezuela.

**Distribution.** Venezuela, Amazon region (Map 4D).

**Metazygia samiria** new species

**Figures 360–364; Map 4D**

**Holotype.** Female holotype and three female paratypes from Rio Samiria, fogging and night collecting, Depto. Loreto, Peru, 8–31 May 1990 (T. Erwin, D. Silva D.), in MUSM, one paratype in MCZ. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace light orange, cephalic region darker, eye area black. Chelicerae brown-black. Labium, endites dusky orange. Sternum orange with sides dusky. Legs orange with indistinct darker dusky rings. Dorsum of abdomen black around anterior, otherwise yellow (Fig. 363). Venter gray to black with a pair of white patches between epigynum and spinnerets and with white anteriorly on sides of pedicel (Fig. 364). Posterior median eyes 0.9 diameter of anterior medians, laterals 0.9 diameter. Anterior median eyes 0.7 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.4 diameters from laterals. Height of clypeus equals 0.7 diameter of anterior median eye. Total length 5.6 mm. Carapace 2.1 mm long, 1.6 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.7, metatarsus 1.9, tarsus 0.7. Second patella and tibia 2.5 mm, third 1.3, fourth 2.1.

**Variation.** Total length of females 4.5 to 5.7 mm. Illustrations were made from the female holotype.

**Diagnosis.** Metazygia samiria differs from *M. ducke* in the shape of the lateral plates in posterior view of the epigynum (Fig. 361).

**Distribution.** Western Amazon region (Map 4D).

**Specimens Examined.** PERU Huánuco: Dantas–La Molina, SW Puerto Inca, 09°28′S, 75°00′W, 22 May 1987, 1♀ (D. Silva D., MUSM); Cucharas, Huallaga Valley, Feb.–Apr. 1954, 1♀ (F. Woytkowski, CAS).

Madre de Dios: 15 km E Puerto Maldonado, 12°33′S, 69°03′W, 26 Feb. 1989, 1♀ (D. Silva D., MUSM); Zona Reservada Tambopata, trocha principal, 290 m, 12°50′S, 69°17′W, 6♀ (D. Silva D., MUSM).

**Metazygia ducke** new species

**Figures 365–369; Map 4D**

**Holotype.** Female holotype from Reserva DUCKE, Manaus, Est. Amazonas, Brazil, Aug. 1971 (M. E. Galiano), in MACN. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace orange. Chelicerae brown. Labium,

Abbreviations. A, terminal apophysis; C, conductor; E, embolus; I, stipes; M, median apophysis; R, radix.

Scale lines. 1.0 mm, genitalia 0.1 mm.
endites brown. Sternum orange, dusky on each side. Coxae and legs orange with distal articles of legs darker. Dorsum of abdomen with dense white pigment spots and an anterior transverse black band (Fig. 368). Venter with a pair of white patches on gray (Fig. 369). Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.6 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 5.0 mm. Carapace 2.1 mm long, 1.5 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.7, metatarsus 1.8, tarsus 0.6. Second patella and tibia 2.3 mm, third 1.2, fourth 1.9.

**Variation.** The specimen from Bolivia has a black sternum and other minor differences.

**Diagnosis.** *Metazygia ducke* differs from *M. samiria* (Fig. 361) by the shape of the lateral plates in posterior view of the epigynum and the square median plate, which has a textured area at its ventral end (Fig. 366).

**Distribution.** Amazon region (Map 4D).

**Metazygia erraticia** (Keyserling), new combination

**Figures 370–373; Map 4E**

*Epeira erraticia* Keyserling, 1883: 197, pl. 15, fig. 3, ♀. Female holotype from "Provinz Amazonas," Brazil, in HECO, examined. Keyserling, 1892: 161, pl. 8, fig. 119, ♀.

*Aranea errans* Roewer, 1942: 841. New name for *erratica*, since thought preoccupied by *Aranea erraticia* Olivier, 1789.

**Description.** Female holotype. Carapace orange. Chelicerae, labium, endites orange. Sternum, coxae, legs light orange. Abdomen whitish (Fig. 373). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.3 diameter apart, 0.7 from laterals. Posterior median eyes 0.6 diameter apart, 1.4 diameters from laterals. Height of clypeus 0.5 diameter of anterior median eye. Legs without macrosetae. Total length 2.9 mm. Carapace 1.4 mm long, 0.9 wide, 0.6 behind lateral eyes. First femur 1.5 mm, patella and tibia 1.7, metatarsus 1.2, tarsus 0.6. Second patella and tibia 1.3 mm, third 0.7, fourth 1.1.

**Variation.** Keyserling records a silvery coloration of the abdomen; the specimens available have lost all pigment. Total length 2.9 to 3.9 mm. Figure 372 was made from the holotype; Figures 370, 371, and 373 are from a specimen from Mato Grosso.

**Diagnosis.** The absence of black in the eye region (Fig. 373) and the thick folded lips of the epigynum in ventral view (Figs. 370, 372) separate *M. erraticia* from *M. samiria* and similar species. All specimens had black amorphous material covering the openings of the epigynum (on the left of Figs. 370–372) which was not found in related species.

**Metazygia manu** new species

**Figures 374–377; Map 4E**

**Holotype.** Male holotype from Puesto de Vigilancia Pakitza, Zona Reservada de Manu, Depto. Madre de Dios, 11°58'S, 71°18'W, Peru, night collecting, 30 Sept. 1987 (D. Silva D., J. Coddington), in MUSM. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Carapace orange, cephalic area gray, black between eyes. Chelicerae, labium, endites black. Sternum black. Coxae light orange; legs orange except for black ring distally on first tibia. Dorsum of abdomen white with anterior transverse black band, and posterior pair of black patches that fuse to a median band above spinnerets (Fig. 376). Venter with distinct black band covering both genital area and spinnerets and continuing into dorsal black patches (Fig. 377).
Carapace with double border above first coxae. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.3 diameter apart, their diameter from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Second tibia thicker than first, with a macroloba on swollen area. Total length 2.7 mm. Carapace 1.24 mm long, 1.04 wide, 0.54 behind lateral eyes. First femur 1.03 mm, patella and tibia 1.18, metatarsus 0.75, tarsus 0.38. Second patella and tibia 1.14 mm, third 0.81, fourth 1.12.

**Diagnosis.** The male palpus differs from others by having a long, fine, "diagonal," embolus (Fig. 374) and by the complex shape of the median apophysis (at 4 hr in Fig. 374, below center of Fig. 375).

**Metazygia genaro new species**

*Figures 378–384; Map 4E*

**Holotype.** Female holotype from Genaro Herrera, 04°55'S, 73°45'W, Depto. Loreto, Peru, 26 Aug. 1988 (D. Silva D.), in MUSM. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace light orange, cephalic region brown, eye area black. Chelicerae dark brown. Labium, endites, sternum brown. Coxae orange; first two legs dark brown, last two orange. Dorsum of abdomen white with a black band around anterior (Fig. 381); venter with a pair of white patches (Fig. 382). Posterior median eyes same diameter as anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.4 diameter apart, 1.1 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.3 mm. Carapace 1.7 mm long, 1.3 wide, 0.7 behind lateral eyes. First femur 1.9 mm, patella and tibia 2.1, metatarsus 1.5, tarsus 0.5. Second patella and tibia 1.8 mm, third 1.1, fourth 1.6.

Male. As in female, but orange areas more yellowish (Fig. 384); venter with a pair of white pigment patches on gray (Fig. 382). Carapace with lobes above first coxae (Fig. 384). Posterior median eyes same diameter as anterior medians, laterals 0.7 diameter. Anterior median eyes 0.8 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.3 diameter apart, 0.8 diameter from laterals. Ocular quadrangle narrower behind than in front. Height of clypeus equals 0.4 diameter of anterior median eye. First coxa with hook, third and fourth each with macroseta on a soft tubercle. Second tibia thicker than first with macrosetae, one of them long. Total length 2.5 mm. Carapace 1.30 mm long, 1.04 wide, 0.48 behind lateral eyes. First femur 1.49 mm, patella and tibia 1.91, metatarsus 1.40, tarsus 0.52. Second patella and tibia 1.31 mm, third 0.80, fourth 1.14.

**Note.** Male and female were matched because in both the anterior dorsal bands of the abdomen are intense black, with white adjacent to the black both anteriorly and posteriorly. Both sexes have a pair of white patches on black on the underside of the abdomen (Fig. 382). Male and female did not come from the same locality.

**Diagnosis.** A broad, triangular epignyal scape as seen in ventral view (Fig. 378) distinguishes the female. Males are distinguished from *M. voxanta* by the shape of the palpal sclerites (Fig. 383).

**Distribution.** Depto. Loreto, Peru (Map 4E).

**Specimen Examined.** PERU Loreto: Rio Manatee [a tributary of the Amazon between Explorers Lodge and Rio Napo], 18 July 1989, grass and shrubs, 1♀ (G. B. Edwards, FSCA).

**Metazygia voxanta new species**

*Figures 385–390; Map 4E*

**Holotype.** Female holotype, female paratype, and two male paratypes from 260 km N Xavantina, 12°49'S, 51°46'W, 400 m, Mato Grosso State, Brazil, campo-grassland, Feb.–Apr. 1969 (Xavantina-Cachimbo Expedition), 1♀ holotype and 1♂ paratype in MCN, others in MCZ. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange, eye region black. Chelicerae, labium, endites brownish. Sternum orange. Coxae, legs orange. Dorsum of ab-
dor men white, with anterior and posterior black marks (Fig. 388). Venter dusky with few irregularly spaced white pigment spots. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.8 diameter apart, 0.5 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.5 diameter of anterior median eye. Total length 2.5 mm. Carapace 0.9 mm long, 0.7 wide, 0.4 behind lateral eyes. First femur 0.8 mm, patella and tibia 1.0, metatarsus 0.6, tarsus 0.4. Second patella and tibia 0.9 mm, third 0.5, fourth 0.7.

Male paratype. Color as in female. The carapace has a lobe above the first coxa (Fig. 390). Posterior median eyes 0.7 diameter of anterior medians, laterals 0.5 diameter. Anterior median eyes 0.3 diameter apart, 0.2 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. First coxa with hook, fourth with one short macroseta. Second tibia thicker than first, with four macrosetae on distal half. Total length 2.0 mm. Carapace 1.0 mm long, 0.8 wide, 0.4 behind lateral eyes. First femur 0.8 mm, patella and tibia 1.1, metatarsus 0.6, tarsus 0.4. Second patella and tibia 0.9 mm, third 0.5, fourth lost.

Note. Males and females were collected together.

Diagnosis. The epigynum has two lobes in ventral view (Fig. 385) and an hourglass-shaped median plate in posterior view (Fig. 386). The male is similar to that of *M. genaro* but has an embolus lamella and a median apophysis of different shape (Fig. 389).

**Metazygia peckorum** new species

Figures 391–400; Map 4F

Holotype. Female from La Chiquita, 5 m elev., 11 km SE San Lorenzo, Esmeraldes Prov., Ecuador, 3–10 June 1975 (S. and J. Peck), in MCZ. The species is named after the collectors.

Description. Female holotype. Carapace light orange, cephalic region dusky. Chelicerae, labium, endites brown. Sternum black. Coxae light orange. First two pairs of legs brown, except for proximal end of femora light orange, last two pairs of legs light orange. Dorsum of abdomen white with anterior dark band (Fig. 399). Venter black with a pair of white patches (Fig. 400). Posterior median eyes 0.8 diameter of anterior medians, laterals 0.6 diameter. Anterior median eyes 0.7 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.1 diameters from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. Total length 4.6 mm. Carapace 1.9 mm long, 1.5 wide, 0.8 behind lateral eyes. First femur 2.0 mm, patella and tibia 2.3, metatarsus 1.7, tarsus 0.6. Second patella and tibia 2.0 mm, third 1.2, fourth 1.8.

Variation. Total length of females 4.0 to 5.1 mm.

Diagnosis. The oval to triangular median area of the epigynum has a longitudinal groove and a minute flat scape at its tip (Figs. 391, 394, 397), and the posterior median plate is constricted dorsally in pos-

Figures 409–413. *M. bahia* n. sp., female. 409–411, epigynum. 409, ventral. 410, posterior. 411, lateral. 412, dorsal. 413, abdomen, ventral.

*Scale lines.* 1.0 mm, genitalia 0.1 mm.
terior view (Figs. 392–395): these characters separate *M. peckorum* from *M. moldira* (Figs. 401, 402).

**Distribution.** From Colombia to Bahia State, Brazil (Map 4F).

**Metazygia moldira** new species

*Figures 401–404; Map 4F.*

**Holotype.** Female holotype from 15 km E Puerto Maldonado, 12°33′S, 69°03′W, 200 m, Depto. Madre de Dios, Peru, 26 Feb. 1989 (D. Silva D.), in MUSM. The specific name is an arbitrary combination of letters.

**Description.** Female holotype. Carapace orange, eye region black. Chelicerae orange with a proximal dusky patch. Labium, endites dusky orange. Sternum light orange. Legs light orange. Dorsum of abdomen white with a black band around anterior (Fig. 404). Venter with a white square between epigynum and spinnerets. Eyes subequal in size. Anterior median eyes their diameter apart, 0.8 diameter from laterals. Posterior median eyes 0.5 diameter apart, 1.2 diameters from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 3.8 mm. Carapace 1.9 mm long, 1.4 wide, 0.8 behind lateral eyes. First femur 2.1 mm, patella and tibia 2.5, metatarsus 1.8, tarsus 0.7. Second patella and tibia 2.3 mm, third 1.3, fourth 1.8.

**Variation.** Total length of females 3.8 to 5.6 mm. Illustrations were made from the female holotype.

**Diagnosis.** *Metazygia moldira* is similar to *M. peckorum*, but the posterior median plate of the epigynum is flake-shaped and widest dorsally (bottom of Fig. 402).

**Distribution.** Western Amazon region (Map 4F).

**Specimens Examined.** ECUADOR Sucumbíos: bridge over Río Cuyabeno, 0.01°S, 76°18′W, 8, 9 Aug. 1988, 1♀ (W. Maddison, MCZ). PERU Loreto: Río Samiria, 8–31 May 1990, 1♀ (T. Erwin, D. Silva D., MUSM).

**Metazygia valentim** new species

*Figures 405–408; Map 4F.*

**Holotype.** Female holotype and two immatures from São Valentim, Est. Río Grande do Sul, Brazil, 16 Oct. 1976 (R. Scherer), in MCN no. 04782. The specific name is a noun in apposition after the type locality.

**Description.** Female holotype. Carapace dusky brown, eye region black. Chelicerae, labium, endites dark brown. Sternum dark brown. Coxae light yellowish; legs light yellowish with tips of tarsi darker. Dorsum of abdomen white with anterior transverse black band; sides with a black patch (Fig. 408). Venter with a black band starting anteriorly from the transverse band and posteriorly enclosing spinnerets. Posterior median eyes same diameter as anterior medians, laterals 0.8 diameter. Anterior median eyes 0.8 diameter apart, 0.7 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.6 diameters from laterals. Laterals 0.5 their diameter apart. Height of clypeus equals 0.8 diameter of anterior median eye. Total length 3.1 mm. Carapace 1.4 mm long, 1.1 wide, 0.6 behind lateral eyes. First femur 1.6 mm, patella and tibia 1.9, metatarsus 1.2, tarsus 0.5. Second patella and tibia 1.6 mm, third 0.8, fourth 1.3.

**Diagnosis.** The epigynum of this species differs from that of other species by having a transverse posterior lip in ventral view (Fig. 405) and a T-shaped posterior median plate in posterior view (Fig. 406).

**Metazygia bahia** new species

*Figures 409–413; Map 4F.*

**Holotype.** Female holotype from Fazenda Jacarandá, Itamaraju, Bahia State, Brazil, 9 Dec. 1977 (J. S. Santos), in MCN no. 11030. The specific name is a noun in apposition after the type locality.
Description. Female holotype. Carapace orange, eye region black. Chelicerae brown. Labium, endites dusky orange. Sternum dusky orange. Legs orange. Dorsum of abdomen with dense white pigment spots and with a black band around anterior (Fig. 412). Venter with indistinct pair of white patches, dusky around spinnerets (Fig. 413). Posterior median eyes 0.9 diameter of anterior medians, anterior laterals 0.7 diameter, posterior 0.8. Anterior median eyes 0.4 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.4 diameter apart, one diameter from laterals. Height of clypeus equals 0.4 diameter of anterior median eye. Total length 4.2 mm. Carapace 2.0 mm long, 1.4 wide, 0.8 behind lateral eyes. First femur 1.9 mm, patella and tibia 2.3, metatarsus 1.6, tarsus 0.6. Second patella and tibia 2.0 mm, third 1.2, fourth 1.6.

Variation. Total length of females 4.0 to 4.3 mm. Illustrations were made from the holotype.

Diagnosis. Unlike the epigynum of M. peckorum (Figs. 391, 392), the two cones on the epigynum of M. bahia are medially separated (Figs. 409, 410).

Distribution. Bahia State to São Paulo State, Brazil (Map 4F).

**Metazygia rothi** new species

**Figures 414, 415; Map 4F**

Holotype. Male holotype from Lomalinda, nr. Puerto Lleras, Depto. Meta, 300 m, 3°18’S, 73°22’W, Colombia, Mar. 1988 (V. Roth), in MCZ. The species is named after the collector.

Description. Male holotype. Carapace olive-white, black between eyes. Chelicerae, labium, endites, sternum, legs olive-white. Dorsum of abdomen white with black band around anterior (Fig. 415). Venter dusky with an indistinct pair of white patches. Posterior median eyes 0.7 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.5 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 diameter from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. Second tibia barely thicker than first, without macrosetae. Total length 2.1 mm. Carapace 1.04 mm long, 0.78 wide, 0.41 behind lateral eyes. First femur 0.96 mm, patella and tibia 1.18, metatarsus 0.78, tarsus 0.37. Second patella and tibia 0.94 mm, third 0.58, fourth 0.78.

Note. This delicate, small male might be that of M. carimagua. A recent molt may have given the specimen its olive-white color.

Diagnosis. Metazygia rothi differs from others by having the sickle-shaped embolus positioned on the conductor and by the shape of the median apophysis and conductor (Fig. 414).

**Metazygia cazeaca** new species

**Figures 416, 417; Map 4I**

Holotype. Male holotype from Jacareacanga, Est. Pará, Brazil, Oct. 1959 (M. Alvarenga), in AMNH. The specific name is an arbitrary combination of letters.

Description. Male holotype. Carapace dark brown, except for light orange median thoracic region. Chelicerae orange. Labium, endites dusky orange. Sternum orange. Coxae light orange, legs orange. Dorsum of abdomen black with a transverse light band (Fig. 417), sides light. Venter with black trapezoid between genital groove and spinnerets. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.5 diameter. Anterior median eyes 0.5 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.3 diameter apart, their diameter from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. Endite without tooth. First coxa with minute hook. (Distal leg articles broken off.) Total length 2.1 mm. Carapace 1.1 mm long, 0.9 wide, 0.5 behind lateral eyes. Third patella and tibia 0.7 mm.

Diagnosis. The coloration of the body,
the elongate shape of the abdomen, widest in posterior half (Fig. 417), and the shape of the sclerites of the palpus (Fig. 416) are unlike any other species of *Metazygia*. This species may not belong to the genus.

*Metazygia cunha* new species

Figures 418, 419; Map 4H

**Holotype.** Male holotype from Jaboticabal, São Paulo State, Brazil, 4 Oct. 1986 (H. F. do Cunha), in MCN no. 17820. The specific name is a noun in apposition after the name of the collector.

**Description.** Male holotype. Carapace yellow, eye region black. Chelicerae, labium, endites yellow. Sternum yellow. Legs yellow. Dorsum of abdomen white, with a band around the anterior and an indistinct, transverse, white patch adjacent and posterior to it (Fig. 419). Venter with a pair of white patches on light gray, with another posterior pair of white spots. Carapace with small lobes (Fig. 419). Median eyes large. Posterior median eyes same diameter as anterior medians, laterals 0.6 diameter. Anterior median eyes 0.4 diameter apart, 0.2 diameter from laterals. Posterior median 0.2 diameter apart, 0.8 diameter from laterals. Height of clypeus equals 0.6 diameter of anterior median eye. First coxa with large hook, third and fourth with a macroseta; the macroseta on the fourth coxa on a tubercle. Total length 3.0 mm. Carapace 1.4 mm long, 1.0 wide, behind lateral eyes 0.5 wide. First femur 1.7 mm, patella and tibia 2.2, metatarsus 1.7, tarsus 0.6. Second patella and tibia 1.5 mm, third 0.9, fourth 1.3.

**Diagnosis.** *Metazygia cunha* differs from others by the shape of the embolus lamella, conductor, and median apophysis (Fig. 418).

*Metazygia aldela* new species

Figures 420–422; Map 4I

**Holotype.** Male holotype from Adeia Araçu, Igarapé Gurupi-Uma, 50 km E of Canindé, Rio Gurupi, Est. Pará, Brazil, 2–30 May 1963 (B. Malkin), in AMNH. The specific name is an arbitrary combination of letters.

**Description.** Male holotype. Carapace light orange, eye region black. Chelicerae, labium, endites brown. Sternum brown. Coxae light orange, legs light orange. Dorsum of abdomen white with black band around anterior (Fig. 424); venter black. Posterior median eyes 0.8 diameter of anterior medians, laterals 0.7 diameter. Anterior median eyes 0.7 diameter apart, 0.3 diameter from laterals. Posterior median eyes 0.2 diameter apart, 1 from laterals. Height of clypeus equals 0.8 diameter of anterior median eye. Carapace with small lobes (Fig. 424). First coxa with large hook, third with one long macroseta and several smaller ones, fourth with one macroseta. Second tibia thicker than first, swollen in middle with two long macrosetae and some others. Total length 2.9 mm. Carapace 1.6
mm long, 1.3 wide, 0.6 behind lateral eyes. First femur 1.7 mm, patella and tibia 2.3, metatarsus 1.7, tarsus 0.6. Second patella and tibia 1.6 mm, third 1.0, fourth 1.5.

**Diagnosis.** The palpus of *Metazygia atama* differs from that of other males by the large median apophysis that faces the cymbium (Fig. 423).

**Metazygia oro** new species

*Figures 425–428; Map 41*

**Holotype.** Male holotype from Rio Colorado, El Oro Prov., Ecuador, 4 Nov. 1942 (R. Walls), in CAS. The specific name is a noun in apposition after the type locality.

**Description.** Male holotype. Carapace dusky orange. Chelicerae orange. Labium,
endites, sternum brown. Legs orange. Abdomen white with a black band around anterior (Fig. 427). Venter black with a pair of white patches (Fig. 428). Carapace with small lobes (Fig. 427). Posterior median eyes same diameter as anterior medians, laterals 0.6 diameter. Carapace with small lobes (Fig. 427). Anterior median eyes 0.8 diameter apart, 0.6 diameter from laterals. Posterior median eyes 0.3 diameter apart, 1.1 diameters from laterals. Height of clypeus equals 1 diameter of anterior median eye. First coxa with large hook, fourth with a short macroseta. Total length 3.1 mm. Carapace 1.5 mm long, 1.2 wide, 0.6 behind lateral eyes. First femur 1.6 mm, patella and tibia 2.1, metatarsus 1.4, tarsus 0.5. Second patella and tibia 1.5 mm, third 0.9, fourth 1.4.

**Diagnosis.** This species is distinguished by the unique shape of the embolus lamella and the median apophysis of the palpus (above center and at 3 hr, respectively, in Fig. 425, at 10 hr and center in Fig. 426).
